## Contacting BMC Software

You can access the BMC Software website at <http://www.bmc.com>. From this website, you can obtain information about the company, its products, corporate offices, special events, and career opportunities.

### United States and Canada

Address	BMC SOFTWARE INC 2101 CITYWEST BLVD HOUSTON TX 77042-2827 USA	Telephone	713 918 8800 or 800 841 2031	Fax	713 918 8000
---------	--	-----------	---------------------------------	-----	--------------

### Outside United States and Canada

Telephone	(01) 713 918 8800	Fax	(01) 713 918 8000
-----------	-------------------	-----	-------------------

If you have comments or suggestions about this documentation, contact Information Development by email at [doc\\_feedback@bmc.com](mailto:doc_feedback@bmc.com).

Oracle and Java are registered trademarks of Oracle and/or its affiliates. Other names may be trademarks of their respective owners.

UNIX is the registered trademark of The Open Group in the US and other countries.

SAP is the trademark or registered trademark of SAP AG in Germany and in several other countries.

The information included in this documentation is the proprietary and confidential information of BMC Software, Inc., its affiliates, or licensors. Your use of this information is subject to the terms and conditions of the applicable End User License agreement for the product and to the proprietary and restricted rights notices included in the product documentation.

## Restricted rights legend

U.S. Government Restricted Rights to Computer Software. UNPUBLISHED – RIGHTS RESERVED UNDER THE COPYRIGHT LAWS OF THE UNITED STATES. Use, duplication, or disclosure of any data and computer software by the U.S. Government is subject to restrictions, as applicable, set forth in FAR Section 52.227-14, DFARS 252.227-7013, DFARS 252.227-7014, DFARS 252.227-7015, and DFARS 252.227-7025, as amended from time to time. Contractor/Manufacturer is BMC Software, Inc., 2101 CityWest Blvd., Houston, TX 77042-2827, USA. Any contract notices should be sent to this address.

## Customer Support

You can obtain technical support by using the Support page on the BMC Software website or by contacting Customer Support by telephone or email. To expedite your inquiry, please see “Before Contacting BMC Software.”

### Support Website

You can obtain technical support from BMC Software 24 hours a day, 7 days a week at <http://www.bmc.com/support>. From this website, you can:

- Read overviews about support services and programs that BMC Software offers.
- Find the most current information about BMC Software products.
- Search a database for problems similar to yours and possible solutions.
- Order or download product documentation.
- Report a problem or ask a question.
- Subscribe to receive email notices when new product versions are released.
- Find worldwide BMC Software support center locations and contact information, including email addresses, fax numbers, and telephone numbers.

### Support by telephone or email

In the United States and Canada, if you need technical support and do not have access to the Web, call 800 537 1813 or send an email message to [customer\\_support@bmc.com](mailto:customer_support@bmc.com). (In the Subject line, enter SupID:<yourSupportContractID>, such as SupID:12345.) Outside the United States and Canada, contact your local support center for assistance.

### Before contacting BMC Software

Have the following information available so that Customer Support can begin working on your issue immediately:

- Product information
  - Product name
  - Product version (release number)
  - License number and password (trial or permanent)
- Operating system and environment information
  - Machine type
  - Operating system type, version, and service pack
  - System hardware configuration
  - Serial numbers
  - Related software (database, application, and communication) including type, version, and service pack or maintenance level
- Sequence of events leading to the problem
- Commands and options that you used
- Messages received (and the time and date that you received them)
  - Product error messages
  - Messages from the operating system, such as file system full
  - Messages from related software

## License key and password information

If you have a question about your license key or password, contact Customer Support through one of the following methods:

- E-mail [customer\\_support@bmc.com](mailto:customer_support@bmc.com). (In the Subject line, enter SupID:<*yourSupportContractID*>, such as SupID:12345.)
- In the United States and Canada, call 800 537 1813. Outside the United States and Canada, contact your local support center for assistance.
- Submit a new issue at <http://www.bmc.com/support>.

# Preface

The *BMC Atrium CMDB 7.6.04 Data Modeling Guide* describes how to model business entities in BMC Atrium CMDB 7.6.04. The guide uses the Common Data Model (CDM) and extensions to that model, and explores recommended practices for using new entities effectively.

The BMC Atrium Configuration Management Database (CMDB) enables you to store and manage information about products and services that are in your environment. The BMC Atrium CMDB uses the term *class* to describe a configuration item (CI) or relationship classification. Each CI is partially classified using some common *attributes* that describe the *base class* (BMC\_BaseElement). Specific details about each class of CI are described by attributes of *subclasses* of BMC\_BaseElement. Relationships are also modeled as a base relationship class (BMC\_BaseRelationship) with subclasses for different types of relationships.

As a provider of BMC Atrium CMDB data, BMC Atrium Discovery products can discover large amounts of configuration data for use by data consumers. BMC Atrium Discovery products are natural enablers for the creation of service models because they can discover many of the components, or CIs, that ultimately make up the service models. These components include:

- Computer systems (including servers, routers, physical and virtual systems, and operating systems)
- Applications
- Software servers (including specialized elements such as SAP®, Sun, Siebel, and mainframe infrastructure components)
- Databases
- Business process definitions
- Network elements

# Audience

This guide is intended for configuration managers, application administrators, asset analysts, and related IT professionals.

## Conventions used in this guide

This guide illustrates how to use the classes that BMC provides for the BMC Atrium CMDB to model a particular business entity, focusing on how you use the entire model rather than on general information about a class or attribute. Although descriptions of classes and attributes are provided to give you context when determining how to model CIs, detailed information such as syntax and the type of attribute is not specified. For that level of information, see the BMC Atrium CMDB 7.6.04 Data Model Help.

This guide applies the following conventions to explain BMC Atrium CMDB concepts in both textual and graphical formats.

## Terminology

In many cases you will be modeling an entity using classes from the CDM, but you might also model part of that same entity using an extension to the CDM. For models that require extensions to the CDM, the term *data model* is used. This guide is organized so that the entities are introduced first in each section, including the recommended practice for that implementation. Any classes and attributes that can be included in the deployment of these business entities in an IT infrastructure are described in an architectural diagram. Where appropriate, recommendations are provided for setting specific attributes for a given class.

Attributes are defined as either *key* or *additional*. Key attributes are those that BMC recommends that you populate for a given class to model a specific CI. Additional attributes are optional attributes that you can populate to further classify a CI or relationship.

## Differentiating Name and ShortDescription attributes

A common misconception is that the caption for the CI on user interfaces and reports is represented by the `Name` attribute, when it is actually the `ShortDescription` attribute. In diagrams in this guide, the names that appear are not from the `Name` attribute, they are the `ShortDescription` attribute (which is usually just a user interface caption). Also, in modeling recommendations, `ShortDescription` is the more user-friendly label, and should always be provided and set with a value that makes sense to an end user.

## Diagrams

Illustrative model diagrams help explain the concepts and modeling recommendations in this guide, and also show how you might model an entity in a real-world business environment. In these diagrams, CIs are represented by single-line boxes that contain attributes of the class or its parent class. Where applicable, key attributes are shown in the box that depicts a specific class and, in some cases, include the recommended value of those attributes.

---

### NOTE

Illustrative diagrams are just examples, and might not reflect every possible class, attribute, or relationship that you would use for modeling all types of the represented object.

---

## Relationships represented in illustrative model diagrams

In the diagrams, boxes illustrate how CIs in your environment should be mapped to the CDM, or how to extend the CDM to create your own data model. Lines are used to represent the type and direction of the relationship.

---

### NOTE

Relationships in the diagrams in this guide are illustrated using Unified Modeling Language (UML) standards. The UML notation may not be consistent with the BMC Atrium CMDB 7.6.04 user interfaces (UI). Some of this discrepancy is due to the absence of a direct UML equivalent to the relationships represented, and some of it is the lack of alignment between the CDM, the UI, and UML standards.

---

Although discrepancies may exist between the UML standards and the BMC Atrium CMDB UI, changes in the UI for future releases of BMC Atrium CMDB will enable the UI to more closely align with UML. In this guide, the conventions applied to the diagrams enable you to easily distinguish which relationship is used in a modeling scenario, regardless of how you might view them in the product.

For example, one major difference between UML standards and the BMC Atrium CMDB UI is that, in the UI, an arrow is always used to represent the source and destination of the relationship, whereas in UML, it is not. Therefore, in this guide, the diagrams more closely align with UML so that you can understand the semantic of the modeling scenario in the context of the corresponding best-practice modeling recommendations.

Although UML does not standardize colors in its rendering of relationships, they are used in the diagrams to help you easily distinguish at a glance which relationship type is recommended to model an example business object. Additionally, the source and destination of each relationship are represented by the letters S and D, respectively. The following section illustrates examples of each relationship type.

## Examples of dependency relationships (arrow)

Dependency relationships are represented by dashed red lines, and contain an arrow to show the direction of the relationship. In a BMC\_Dependency relationship, the arrow starts at A, the dependent (Destination), and ends at B, the antecedent (Source) of the relationship. Entity A is dependent on Entity B.

## Example of a collection relationship (circle)

A BMC\_MemberOfCollection relationship is represented by green lines with circle tips, as illustrated in the following diagram:

A is the collection class (Source), and B is the member class (Destination). The circle represents a collection relationship, where the collection class uses properties of the member class.

## Example of a component relationship (diamond)

In a component relationship, the source CI is a group that has a component or part; its destination. Entity A is a group (Source) that has a component B (Destination). In diagrams, component relationships are represented by green lines with diamond tips.

## Cardinality in relationships

Every relationship class has a cardinality that defines how many instances of the source class can be related to each instance of the destination class and vice versa. Where cardinality is specified in the diagrams, it is shown at the ends of the relationship lines as one of the following types:

- 1:1 (one to one)
- 1:\* (one to many)
- \*:1 (many to one)
- \*:.\* (many to many)

## Weak relationships

Where a *weak relationship* exists between two instances, that relationship is indicated by the letter W in the illustrative model diagrams. If the relationship is a weak relationship, its destination member, called the *weak* member, cannot exist without its source member, called the *strong* member. A weak relationship creates a logical composite object consisting of both member CIs.

# BMC Atrium Core documentation

This section describes the complete set of BMC Atrium CMDB documentation, including manuals, help systems, videos, and so on.

Unless otherwise noted, documentation is available free of charge on the BMC Atrium CMDB documentation media (DVD or Electronic Product Download bundle) and on the BMC Customer Support site, at <http://www.bmc.com/support>.

To find this documentation on the BMC Customer Support site, choose Product Documentation > Supported Product A-Z List > BMC Atrium CMDB Enterprise Manager > 7.6.04

Title	Description	Audience
<i>Atrium Integrator 7.6.04 User's Guide</i>	Information about defining source and target connections, creating jobs and transformations, editing and monitoring jobs, and other Atrium Integrator concepts.	Users who are responsible for setting up data transfer integrations between external data stores and BMC Atrium CMDB.
<i>BMC Atrium CMDB 7.6.04 Administrator's Guide</i>	Information about setting permissions, configuring federation, modifying the data model, configuring an impact model, and other administrative tasks in BMC Atrium Configuration Management Database (BMC Atrium CMDB).	Configuration managers, application administrators, and asset analysts.
<i>BMC Atrium CMDB 7.6.04 Common Data Model Diagram</i>	Hierarchical diagram of all classes in the Common Data Model (CDM), including unique attributes and applicable relationships.	Configuration managers, application administrators, and asset analysts.

Title	Description	Audience
BMC Atrium CMDB 7.6.04 Data Model Help	Description and details of superclasses, subclasses, attributes, and relationship classes for each class. Contains only information about the CDM at first, but you can update it to include information about data model extensions that you install.  <b>Note:</b> This Help is provided in HTML and is available on the BMC Atrium CMDB media. It is not available on the BMC Customer Support site.	Configuration managers, application administrators, and asset analysts.
<i>BMC Atrium CMDB 7.6.04 Data Modeling Guide</i>	Best practices for using the classes that BMC provides for BMC Atrium CMDB (both the CDM and extensions) to model complex business entities, focusing on the use of multiple related CIs to model an entity rather than on general information about a class or attribute.	Configuration managers, application administrators, and asset analysts.
BMC Atrium CMDB 7.6.04 Javadoc Help	Information about Oracle Java classes, methods, and variables that integrate with BMC Atrium CMDB.  <b>Note:</b> This Help is provided in HTML and is available on the BMC Atrium CMDB media. It is not available on the BMC Customer Support site.	Application programmers.
<i>BMC Atrium CMDB 7.6.04 Normalization and Reconciliation Guide</i>	Information about normalizing data in BMC Atrium CMDB and reconciling CIs from different data providers into a single production dataset.	Configuration managers, application administrators, and asset analysts.
BMC Atrium CMDB 7.6.04 Online Help	Help for using and configuring BMC Atrium CMDB, including Atrium Integrator, BMC Atrium Product Catalog, Reconciliation Engine, Normalization Engine, and so on.  <b>Note:</b> This Help is provided in HTML and is available through the Help links in the BMC Atrium CMDB user interface. It is not available on the BMC Customer Support site.	Configuration managers, application administrators, asset analysts, and users that work with CIs and need to understand the relationships that exist within BMC Atrium CMDB.
<i>BMC Atrium CMDB 7.6.04 User's Guide</i>	Information about using BMC Atrium CMDB, including searching for and comparing CIs and relationships, relating CIs, viewing history, running impact simulations, and viewing federated data.	Users that work with CIs and need to understand the relationships that exist within BMC Atrium CMDB.
<i>BMC Atrium Core: Taking Your Data Into Production End to End</i>	End-to-end high-level steps for bringing data into BMC Atrium CMDB from a third-party source and making it available in your production dataset.  <b>Note:</b> This Flash video is available on the BMC Atrium CMDB media. It is not available on the BMC Customer Support site.	Configuration managers, application administrators, and asset analysts.

Title	Description	Audience
<i>BMC Atrium Core 7.6.04 Compatibility Matrix</i>	<p>Information about the BMC Atrium CMDB configurations that are expected to work together based on design, testing, or general understanding of the interaction between products.</p> <p><b>Note:</b> Download the <i>BMC Atrium Core 7.6.04 Compatibility Matrix</i> from the BMC Customer Support site at <a href="http://www.bmc.com/support/reg/remedy-compatibility-tables.html?c=n">http://www.bmc.com/support/reg/remedy-compatibility-tables.html?c=n</a>.</p>	Configuration managers, application administrators, and asset analysts.
<i>BMC Atrium Core 7.6.04 Concepts and Planning Guide</i>	Information about CMDB concepts and high-level steps for planning and implementing BMC Atrium CMDB.	Anyone who wants to learn about and understand BMC Atrium CMDB products, CMDBs in general, and the functionality of BMC Atrium CMDB in particular. IT leaders, configuration managers, application administrators, and asset analysts are some who will benefit from this information.
<i>BMC Atrium Core 7.6.04 Developer's Reference Guide</i>	Information about creating API programs using C API functions and data structures.	Application administrators and programmers.
<i>BMC Atrium Core 7.6.04 Installation Guide</i>	Information about installing, upgrading, and uninstalling BMC Atrium Core features.	Application administrators.
<i>BMC Atrium Core 7.6.04 Master Index</i>	Combined index of all guides.	Everyone.
<i>BMC Atrium Core 7.6.04 Product Catalog and DML Guide</i>	Information about configuring the Product Catalog and DML, adding products, and creating aliases for products, manufacturers, and categorizations.	System administrators, IT managers, network managers, and other qualified personnel who are familiar with their computing and networking environment.
<i>BMC Atrium Core 7.6.04 Release Notes</i>	Information about new features, known issues, and other late-breaking topics.	Everyone.
<i>BMC Atrium Core 7.6.04 Troubleshooting Guide</i>	Information about resolving issues with BMC Atrium CMDB components, including API, filter, and console error messages and their solutions.	Application administrators, programmers, and BMC Support personnel.
<i>BMC Atrium Core 7.6.04 Web Services Help</i>	<p>Information about using BMC Atrium Core Web Services, including how to publish and find interfaces in the Web Services Registry, set versions, disambiguate web services, configure security policies and encryption, and use BMC Atrium Core Web Services data structures and operations.</p> <p><b>Note:</b> This Help is provided in HTML and is available on the BMC Atrium CMDB media. It is not available on the BMC Customer Support site.</p>	Application administrators and programmers.

Title	Description	Audience
<i>BMC Atrium Integration Engine 7.6.04 ADK Developer's Guide</i>	Information about how to build adapters that can transfer information between an external data store and either BMC Remedy AR System forms or BMC Atrium CMDB.	Developers who have a basic understanding of BMC Atrium Integration Engine and want to build adapters that can exchange data between two data sources.
BMC Atrium Integration Engine 7.6.04 Online Help	<p>Help for using and configuring BMC Atrium Integration Engine.</p> <p><b>Note:</b> This Help is provided in HTML and is available through the Help links in the BMC Atrium Integration Engine user interface. It is not available on the BMC Customer Support site.</p>	Users who are responsible for setting up data transfer integrations between external data stores and either BMC Atrium CMDB or BMC Remedy AR System.
<i>BMC Atrium Integration Engine 7.6.04 User's Guide</i>	Information about creating data exchanges and data mappings, defining rules and queries, activating event-driven data exchanges, defining connection settings, and other BMC Atrium Integration Engine concepts.	Users who are responsible for setting up data transfer integrations between external data stores and either BMC Atrium CMDB or BMC Remedy AR System.
<i>Mapping Your Data to BMC Atrium CMDB 7.6.04 Classes</i>	Spreadsheet that maps common IT objects to the appropriate class, whether part of the CDM or an extension. This spreadsheet also includes information about further categorizing instances using key attributes, and best practices for creating normalized relationships.	Configuration managers, application administrators, and asset analysts.

# Computer system modeling

This section describes how to use the CDM to model computer systems (servers, workstations, and network nodes such as routers, switches, and hubs). It details the classes, relationships, and attributes used to model computer systems, operating systems, hardware components, software inventory and patches, access points, and network interfaces.

For information on modeling applications, including modeling runtime versus installed aspects of applications, see Chapter 2, “Application modeling.”.

The following topics are provided:

- Logical identity of BMC\_ComputerSystem (page 18)
- Computer system modeling (page 21)
- Software inventory and patch modeling (page 22)
- Router modeling (page 24)
- Virtual system modeling (page 25)
- Operating system modeling (page 33)
- Hardware component modeling (page 34)
- Access point modeling (page 36)
- Network interface and address modeling (page 38)
- Software and hardware cluster modeling (page 41)

# Logical identity of BMC\_ComputerSystem

BMC\_ComputerSystem is a class that stores CIs relating to collections of managed system elements. This is the primary class that you use to model the computers in your organization. You can use the attributes in this class to identify the purpose of each computer CI in your organization.

For example, the class contains several attributes that represent any network-addressable system, such as a server, a workstation, or a network device (router, switch, hub, load balancer, firewall, and so forth), as well as mainframes, printers, and virtual systems. Table 1-1 shows the key attributes that identify an instance of BMC\_ComputerSystem.

**Table 1-1: Key attributes for BMC\_ComputerSystem**

Attribute	Usage
Name, NameFormat	Identifies a computer system. The Name attribute should be a unique instance identifier that may not be Human Readable. Because multiple valid naming conventions may exist and can be used according to specific contexts, set the NameFormat attribute with a value indicating the heuristic used to generate the Name value. For example, in some cases, an instance of BMC_ComputerSystem will be identified by an external DNS name (a name configured in a DNS server). In other cases, a static IP address will be used. The naming conventions for NameFormat are: <ul style="list-style-type: none"> <li>■ IP—a valid IP address (decimal bytes delimited with dots).</li> <li>■ DNS—a fully qualified host name, formatted as a HostName and a DomainName delimited with dots (the DomainName can also be made of multiple components delimited with dots).</li> <li>■ TOKEN—Name holds a value defined by the TokenId (see “Additional attributes for BMC_ComputerSystem” on page 20 for more information on the TokenId).</li> </ul>
Domain	Identifies the domain name of the computer, as known by the end points.
HostName	Specifies the local name of the computer, as known by the end points. This value must be set according to BMC nationalization guidelines that specifies the algorithms and methods required to obtain the correct values.
SerialNumber	Specifies the serial number of the computer.

## Key attributes of BMC\_ComputerSystem

Table 1-2 show the attributes that further describe the role of an instance of BMC\_ComputerSystem.

**Table 1-2: The role of an instance of BMC\_ComputerSystem (Sheet 1 of 2)**

Attribute	Usage		
CapabilityList	<p>Defines the main functions that the computer can perform.</p> <p>This is a character attribute in which you can enter any value listed in the description. You can enter more than one of these values; however, make sure that multiple values are delimited by commas. A computer system can be dedicated to a single function, such as printing, routing, or switching packets, or it can perform several functions. Typically, the PrimaryCapability attribute is set to the first value specified in CapabilityList.</p> <p>The following list illustrates the functions and values to assign to a CapabilityList attribute depending on the function of the computer.</p> <table> <tr> <td> <ul style="list-style-type: none"> <li>■ Not Dedicated—0</li> <li>■ Unknown—1</li> <li>■ Other—2</li> <li>■ Storage—3</li> <li>■ Router—4</li> <li>■ Switch—5</li> <li>■ Layer 3 Switch—6</li> <li>■ Central Office Switch—7</li> <li>■ Hub—8</li> <li>■ Access Server—9</li> <li>■ Firewall—10</li> <li>■ Print—11</li> <li>■ I/O—12</li> <li>■ Web Caching—13</li> <li>■ Server—14</li> <li>■ Management —15</li> <li>■ Block Server —16</li> <li>■ File Server —17</li> <li>■ Mobile User Device —18</li> <li>■ Repeater—19</li> <li>■ Bridge/Extender—20</li> <li>■ Gateway —21</li> <li>■ LoadBalancer—22</li> <li>■ Mainframe—23</li> <li>■ SANSwitch—24</li> <li>■ SANHub—25</li> </ul> </td><td> <ul style="list-style-type: none"> <li>■ SANBridge—26</li> <li>■ SANRouter—27</li> <li>■ SANDirector—28</li> <li>■ RAIDStorageDevice—29</li> <li>■ Virtual Tape Library—30</li> <li>■ JBOD—31</li> <li>■ Workstation—32</li> <li>■ StorageSubsystem—33</li> <li>■ Storage Virtualizer—34</li> <li>■ Media Library—35</li> <li>■ ExtenderNode—36</li> <li>■ NAS Head—37</li> <li>■ Self-contained NAS—38</li> <li>■ UPS—39</li> <li>■ IP Phone—40</li> <li>■ Management Controller—41</li> <li>■ Chassis Manager—42</li> <li>■ Host-based RAID controller—43</li> <li>■ Storage Device Enclosure—44</li> <li>■ Desktop—45</li> <li>■ Laptop—46</li> <li>■ Virtual Library System—47</li> <li>■ Blade System—48</li> <li>■ Blade Server—49</li> </ul> </td></tr> </table>	<ul style="list-style-type: none"> <li>■ Not Dedicated—0</li> <li>■ Unknown—1</li> <li>■ Other—2</li> <li>■ Storage—3</li> <li>■ Router—4</li> <li>■ Switch—5</li> <li>■ Layer 3 Switch—6</li> <li>■ Central Office Switch—7</li> <li>■ Hub—8</li> <li>■ Access Server—9</li> <li>■ Firewall—10</li> <li>■ Print—11</li> <li>■ I/O—12</li> <li>■ Web Caching—13</li> <li>■ Server—14</li> <li>■ Management —15</li> <li>■ Block Server —16</li> <li>■ File Server —17</li> <li>■ Mobile User Device —18</li> <li>■ Repeater—19</li> <li>■ Bridge/Extender—20</li> <li>■ Gateway —21</li> <li>■ LoadBalancer—22</li> <li>■ Mainframe—23</li> <li>■ SANSwitch—24</li> <li>■ SANHub—25</li> </ul>	<ul style="list-style-type: none"> <li>■ SANBridge—26</li> <li>■ SANRouter—27</li> <li>■ SANDirector—28</li> <li>■ RAIDStorageDevice—29</li> <li>■ Virtual Tape Library—30</li> <li>■ JBOD—31</li> <li>■ Workstation—32</li> <li>■ StorageSubsystem—33</li> <li>■ Storage Virtualizer—34</li> <li>■ Media Library—35</li> <li>■ ExtenderNode—36</li> <li>■ NAS Head—37</li> <li>■ Self-contained NAS—38</li> <li>■ UPS—39</li> <li>■ IP Phone—40</li> <li>■ Management Controller—41</li> <li>■ Chassis Manager—42</li> <li>■ Host-based RAID controller—43</li> <li>■ Storage Device Enclosure—44</li> <li>■ Desktop—45</li> <li>■ Laptop—46</li> <li>■ Virtual Library System—47</li> <li>■ Blade System—48</li> <li>■ Blade Server—49</li> </ul>

**Table 1-2: The role of an instance of BMC\_ComputerSystem (Sheet 2 of 2)**

Attribute	Usage
PrimaryCapability	Describes the main function that the computer performs. By convention, PrimaryCapability is the first item in the CapabilityList attribute.
ShortDescription	Specifies a short description for the instance when the value of the Name attribute is encoded. ShortDescription should always be provided and set with a value that makes sense to an end user.

For example, a server with active firewall capabilities could have the values 14 (Server) or 10 (Firewall) for CapabilityList. PrimaryCapability would be set to Server if this is the main function of the system. However, a switch device would have CapabilityList = 5 (Switch) and PrimaryCapability = 5.

## Additional attributes for BMC\_ComputerSystem

Table 1-3 describes the attributes that provide additional information about an instance of BMC\_ComputerSystem.

**Table 1-3: Additional information for BMC\_ComputerSystem**

Attribute	Description
Description	The functions that the computer system can perform.
DHCPUse	Specifies whether the system is configured to use DHCP: Enabled = configured to use DHCP Disabled = not configured to use DHCP
ManufacturerName	The company that manufactured the computer.
Model	The model of the computer.
OwnerContact	The contact information that specifies how the primary system owner can be reached (such as phone number or email address).
OwnerName	The name of the primary system owner.
TokenId	A unique identifier populated by BMC Discovery products and used by the Reconciliation Engine (of the BMC Atrium CMDB) to identify instances.
TotalPhysicalMemory	The total physical memory, in kilobytes.

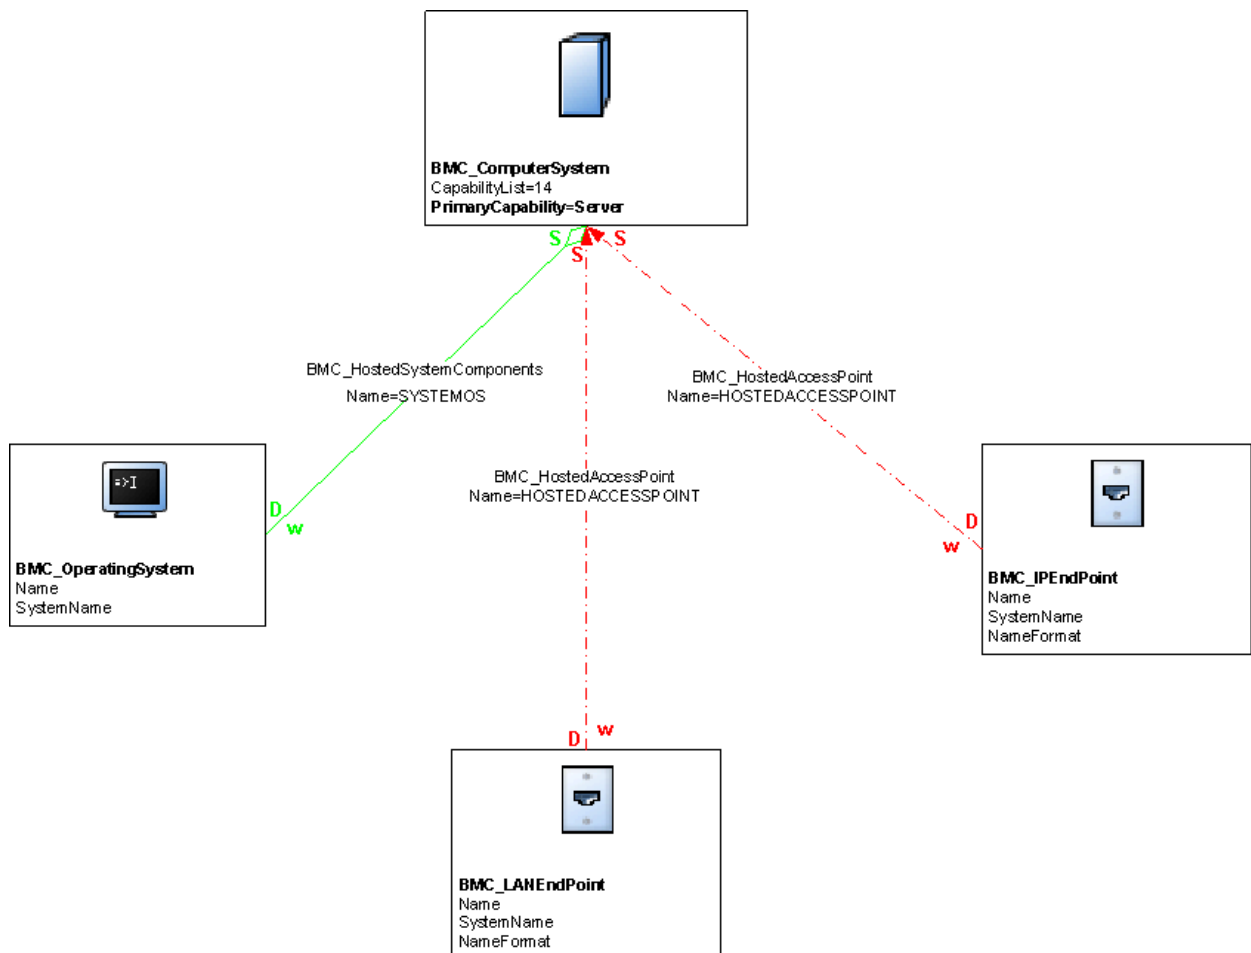

For more information about specific attributes, see the BMC Atrium CMDB 7.6.04 Common Data Model Help.

# Computer system modeling

Computer systems are parent objects that may be represented as an aggregation of component parts (such as operating systems, hardware, software inventory, or network addresses) that are child instances related to the `BMC_ComputerSystem` instance.

Systems provide computing capabilities and aggregate one or more of these elements: file systems, operating systems, processors, and memory (including volatile and nonvolatile storage). Therefore, additional information about a computer system might not be part of a `BMC_ComputerSystem` instance but be available from instances of other classes connected to the `BMC_ComputerSystem` instance through relationships. For example, Figure 1-1 represents a model for a server, a network-addressable computer system.

Figure 1-1: Illustrative model of a server

Servers, workstations, network devices (such as routers, switches, hubs, load balancers, or firewalls) are all instances of `BMC_ComputerSystem`, the class representing all network addressable systems. `BMC_ComputerSystem` represents an entity made up of component parts that operate as a functional whole.

The `PrimaryCapability` attribute is crucial to identifying whether a specific instance is a server, a router, or something else. BMC Atrium CMDB planners might use the `PrimaryCapability` attribute to define a vendor-specific switch used in their network, making it easy to import this data from a vendor’s environment as an industry-standard item in their BMC Atrium CMDB.

## Software inventory and patch modeling

Software inventory represents the products and patches that are installed on a computer. `BMC_Product` represents instances of installed products, whereas `BMC_Patch` represents instances of patches (operating system patches and product patches). Figure 1-2 illustrates an example model of a server with two installed products.

Figure 1-2: Illustrative model of a software inventory containing two installed products

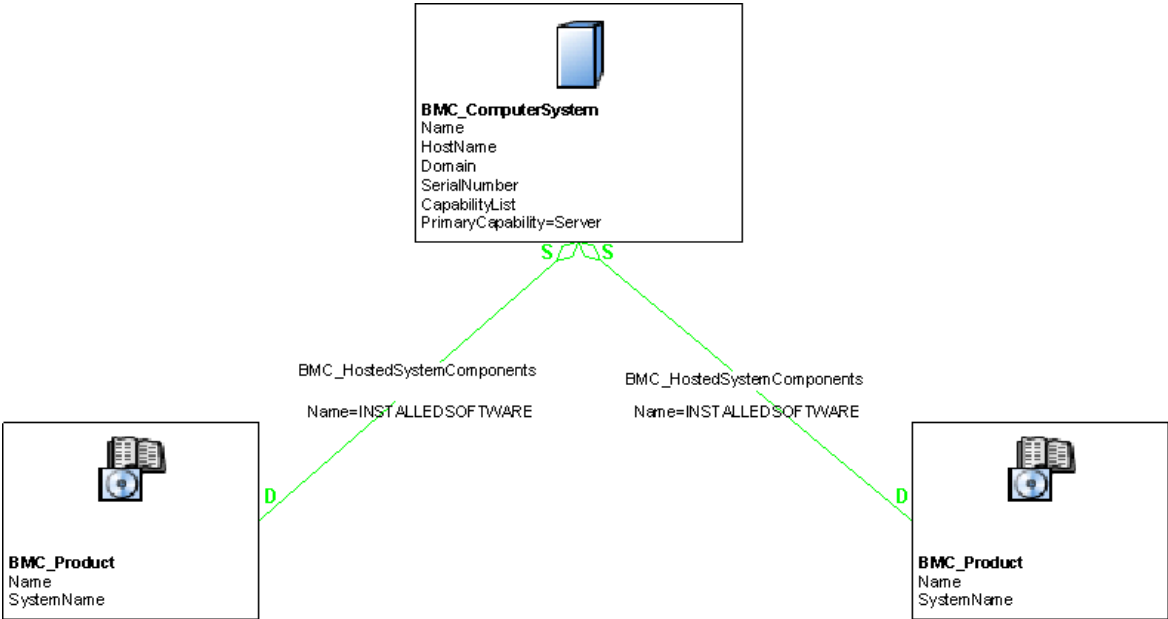

Figure 1-3 illustrates an example model of a server with one installed patch.

Figure 1-3: Illustrative model of a software inventory with a patch

You might not want to model patches in your BMC Atrium CMDB in all cases. For example, you might store patches for servers in the BMC Atrium CMDB, but it might not be necessary to do so for desktops and routers.

Both `BMC_Product` and `BMC_Patch` are subclasses of `BMC_Software` and `BMC_SystemComponent`. You should associate each instance of a product or of a patch to the parent instance of `BMC_ComputerSystem` by the `BMC_HostedSystemComponents` relationship. When modeling software inventory, be aware that the `BMC_Product` class captures only installed products or applications, not runtime aspects.

For more information about modeling runtime applications and using instances of `BMC_Product` for application modeling, see Chapter 2, “Application modeling.”

## Logical identity of `BMC_ComputerSystem` (for products or patches)

Like any child instance of `BMC_ComputerSystem`, a product or a patch is identified by the `Name` attribute in conjunction with the `SystemName` attribute that represents the name of the computer instance. Thus, the `Name` attribute represents the local name of the CI in the context of the computer that is hosting it, as described in Table 1-4.

**Table 1-4: Key attributes for `BMC_ComputerSystem`**

Attribute	Usage
<code>Name</code>	Identifies the child instance in the context of the parent instance of <code>BMC_ComputerSystem</code> .
<code>SystemName</code>	Specifies the name of the computer instance. This must be the same as the parent instance of the <code>BMC_ComputerSystem</code> <code>Name</code> attribute. This attribute is automatically populated from the related CI when a weak relationship is created between the computer system and the product or patch.

## Additional attributes of `BMC_ComputerSystem` (for products or patches)

Table 1-5 describes attributes that provide additional information about products and patches.

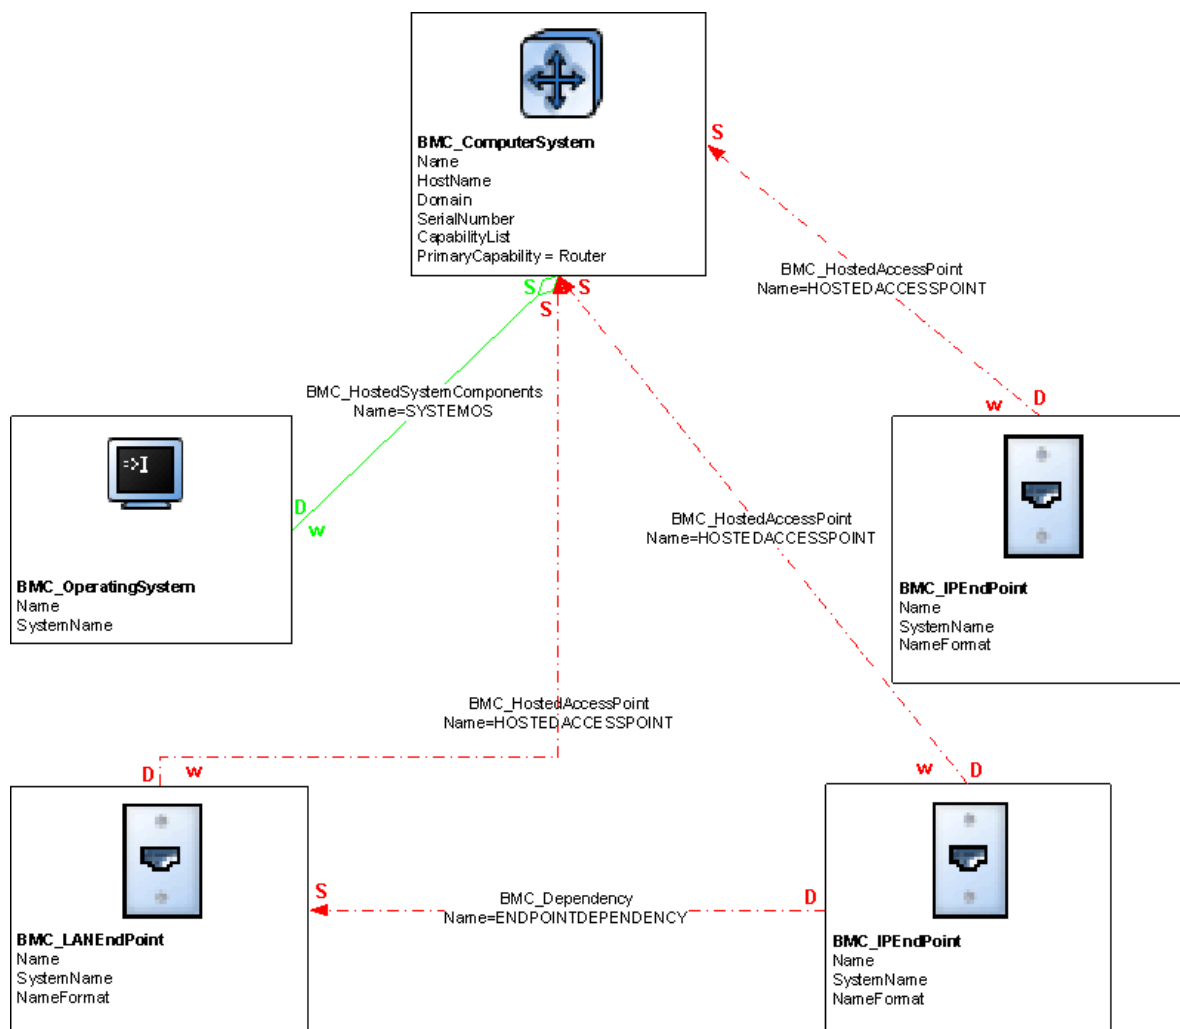

**Table 1-5: Additional information about products and patches**

Attribute	Description
<code>Description</code>	The description for the component.
<code>ManufacturerName</code>	The company that manufactured the component.
<code>SerialNumber</code>	The serial number of the component.
<code>ShortDescription</code>	A caption for the component.
<code>PatchNumber</code>	The version number of the patch.
<code>VersionNumber</code>	The version number of the component.

# Router modeling

Routers are modeled using the `BMC_ComputerSystem` class by setting the `PrimaryCapability` attribute to Router. Figure 1-4 illustrates an example model of a network router.

Figure 1-4: Illustrative model of a router

In the model, two `BMC_IPEndpoint` classes are used to represent the interfaces to the router.

# Virtual system modeling

Virtual systems represent one or more virtual machines that are hosted by a physical computer. A virtual system has the same relationships to subcomponents and applications that a physical system does. In other words, a virtual system has an operating system (such as Windows or UNIX<sup>®</sup>), network addresses, and software. The major difference is that these subcomponents, although captured as regular CIs, are all virtual. Additionally, virtual systems can have BMC\_Genealogy relationships that define relationships between a parent virtual system and its child virtual systems. For example, If you have a virtual system named win2k-vm1 and a clone of that system named win2k-vm2, the win2k-vm1 system is the parent and the win2k-vm2 system is the child.

When modeling virtualization in your environment, represent the virtual computer system using the BMC\_ComputerSystem class, and the virtualization software (such as Hypervisor or virtualization software), using the BMC\_VirtualSystemEnabler class.

An example of a virtual system model is illustrated in Figure 1-5.

**Figure 1-5: Illustrative model of a virtual system without resource pools and settings**

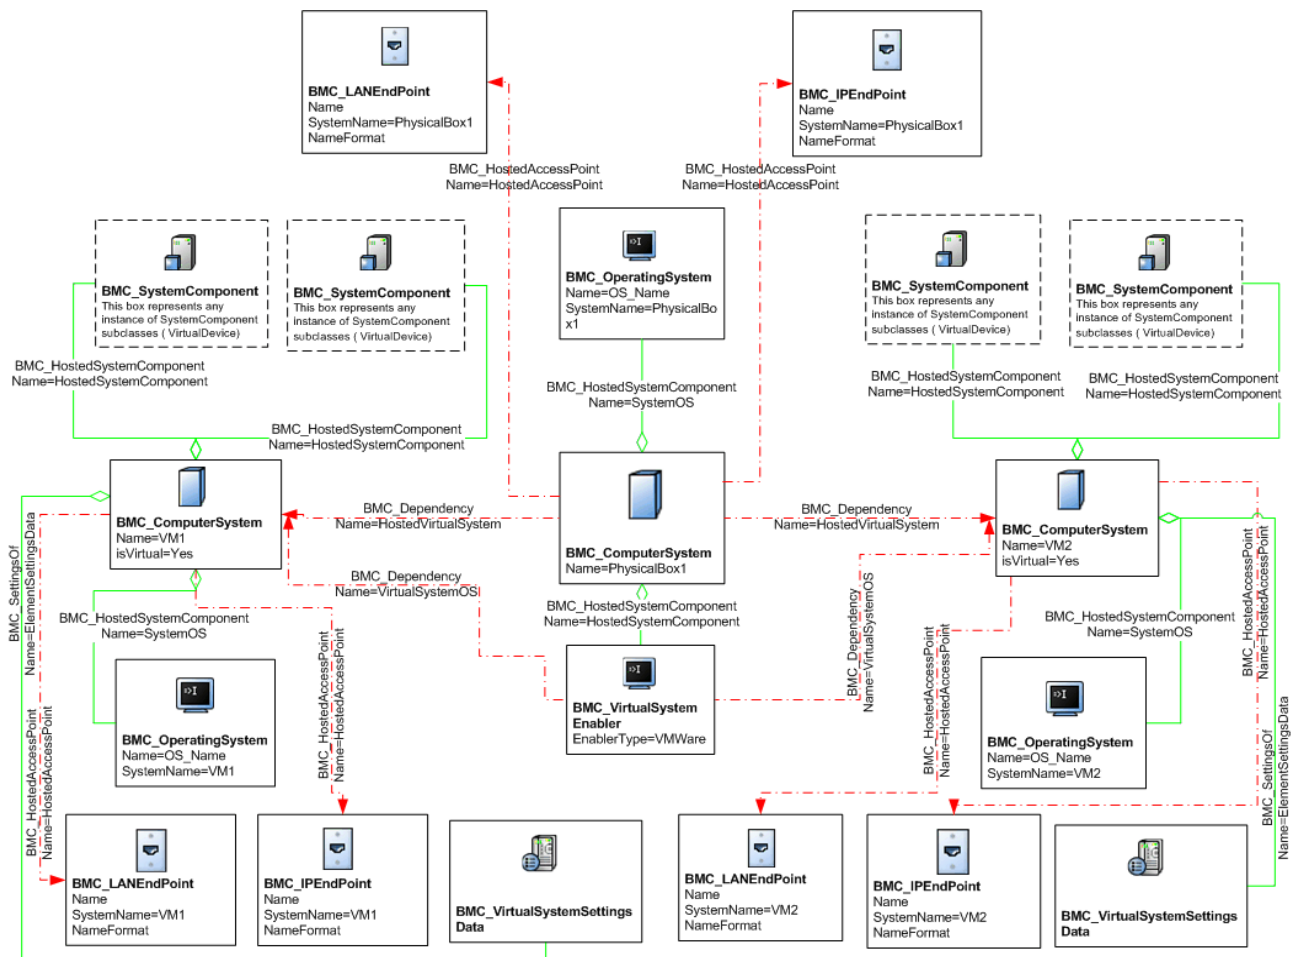

Figure 1-5 illustrates multiple virtual systems (virtual machines, or VMs), the physical computer system that hosts them, and the virtualization operating system, which is hosted on the physical system and runs the VMs. The diagram is simplified and does not contain resource pools.

## Logical identity of BMC\_System and BMC\_ComputerSystem (for virtual systems)

You model virtual systems as instances of `BMC_ComputerSystem`, a subclass of `BMC_System`. You should follow the same naming rules as for an instance of `BMC_ComputerSystem` class. For more information about this class, see “Logical identity of `BMC_ComputerSystem`” on page 18.

The key attributes for defining virtual systems are `VirtualSystemType` (for the `BMC_ComputerSystem` class) and `isVirtual` (for the `BMC_System` and `BMC_SystemComponent` classes and their subclasses). Both attributes are described in Table 1-6.

Table 1-6: Key attributes for defining virtual systems

Attribute	Usage
<code>VirtualSystemType</code>	Identifies the type of virtual machine. Values are Other (0), Unknown (1), PR/SM (2), z/VM (3), VMWare (4), Xen (10), Hyper-V (15), Sun Solaris™ Container (20), VPar (25), NPar (30) and LPar (35).
<code>isVirtual</code>	Specifies whether the instance is virtual or physical. Values are NULL, No (0), or Yes (1). If you know that it is a virtual machine, use Yes. If you know that it is a physical machine, use No. If you are unsure, use NULL.

**NOTE**

In BMC Atrium CMDB 7.6.00, the `isVirtual` attribute was moved from the `BMC_ComputerSystem` class to the `BMC_System` and `BMC_SystemComponent` classes. This move expands the virtualization scope beyond computer systems, enabling you to model potential future virtualizable entities, such as applications. Because `BMC_ComputerSystem` is a subclass of the `BMC_System` class, the `isVirtual` attribute is still available in the `BMC_ComputerSystem` class.

To ensure correct reconciliation with data created by BMC Software products, use NULL instead of No for the `isVirtual` attribute to represent an instance that is not virtual.

## Logical identity of BMC\_VirtualSystemEnabler

The BMC\_VirtualSystemEnabler class stores information about software that enables a collection of virtual computer systems to run on a single physical computer system (for example, VMware). This class is used to capture the virtualization OS, such as operating systems that run virtual machines (including VMware images, Solaris zones, IBM® AIX® logical partitions, HP-UX virtual partitions, and so forth).

The BMC\_VirtualSystemEnabler class is associated to the parent computer system instance by the BMC\_HostedSystemComponents relationship. As a subclass of BMC\_ComputerSystem, any instance (representing a new business CI) of the BMC\_VirtualSystemEnabler class is identified, at minimum, by the Name and SystemName attributes.

The key attribute for BMC\_VirtualSystemEnabler is EnablerType, described in Table 1-7.

**Table 1-7: Key attributes for EnablerType**

Attribute	Usage
EnablerType	Specifies the virtualization software or OS. The possible values are Other (0, the default), Unknown (1), PR/SM (2), z/VM (3), VMWare Server (4), Solaris Resource Manager (5), LPar (6), VPar (7), HP nPartitions (20), Integrity VM (25), Microsoft Hyper-V (30), VMWare ESX Server (35), VMWare Workstation (40), Xen Hypervisor (45), and LDOM Hypervisor (50).

For a complete list of attributes for the BMC\_VirtualSystemEnabler class, see the BMC Atrium CMDB 7.6.04 Data Model Help.

## Logical identity of BMC\_VirtualSystemSettingData

The BMC\_VirtualSystemSettingData class (derived from BMC\_Settings) provides additional granularity about a virtual system's settings through a set of virtualization-specific properties.

Key attributes for defining the virtual aspects using the BMC\_VirtualSystemSettingData class are described in Table 1-8.

**Table 1-8: Key attributes for BMC\_VirtualSystemSettingData (Sheet 1 of 2)**

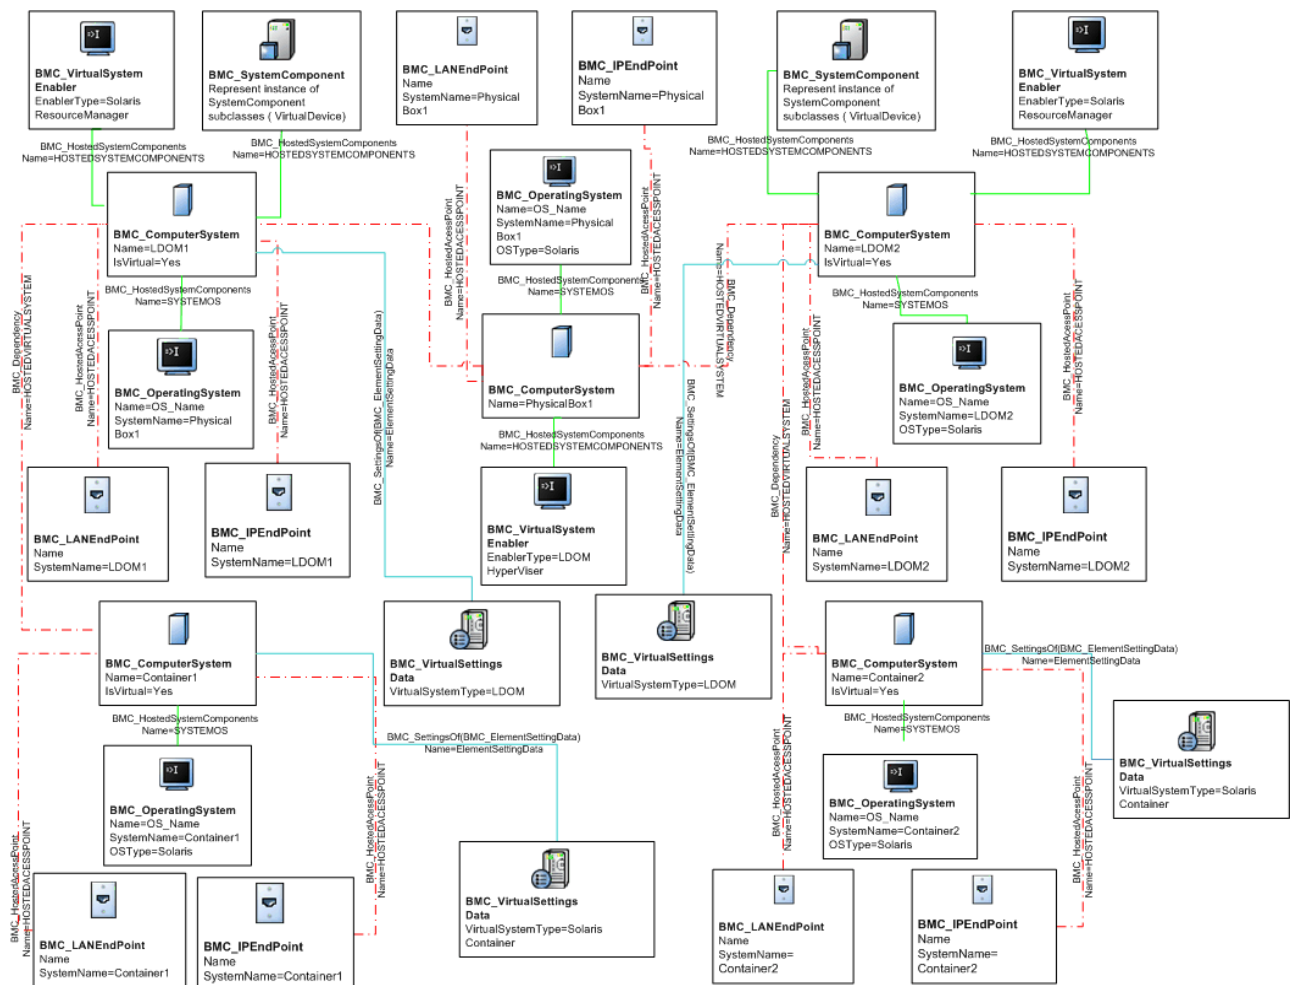

Attribute	Usage
VirtualSystemState	Specifies the state of the virtual machine. Values are Other (0), Unknown (1), Active (10), InActive (15), Suspended (20), and Disabled (25).
VirtualSystemType	Specifies a type of virtual system. Values are Other (0), Unknown (1), LPAR (2), VM/VM Guest (3), VMware (4), Xen (20), LDOM (25), Solaris Container (30), HP nPartitions (35), VPar (40), and Microsoft Hyper-V (45).
ActualProvisionDate	The date and time that a specific VM was provisioned. This attribute is important for enabling successful reporting on BMC Dashboards.

Table 1-8: Key attributes for BMC\_VirtualSystemSettingData (Sheet 2 of 2)

Attribute	Usage
ProposedDecommissionDate	<p>The date and time that the VM will be removed from the environment. One of the biggest problems causing virtual system sprawl is that organizations do not decommission VMs and track the information. This attribute helps to drive workflow actions such as:</p> <ul style="list-style-type: none"><li>■ Notifying users that their VM is about to be decommissioned and enabling them to extend the time before that occurs.</li><li>■ Automatically creating change requests to begin the decommissioning process.</li><li>■ Automatically starting a job in BMC BladeLogic, BMC Atrium Orchestrator, and other consuming applications to decommission the VM.</li></ul>
ActualDecommissionDate	<p>The date of the actual decommission. There can be an extension to that date to enable you to report or track a VM.</p> <p>You can also compare differences between the decommission date and actual decommission date, or block future updates to the extension date.</p>

Figure 1-6 displays an organization that has a virtual system environment, where a Solaris server is divided into two domains (LDOM1 and LDOM2), which are further divided into containers (Container1 and Container2).

Figure 1-6: Logical domain virtual systems with settings and containers

## Best Practice

The recommended best practice for modeling this scenario would be:

For the virtualization environment, use `BMC_ComputerSystem`, where the `isVirtual` attribute is set to `Yes`. The parent system, which is either virtual or physical has to be related to the virtual system with a `BMC_Dependency` relationship where the attribute `Name` has a value of `HostedVirtualSystem`. To model the virtualization technology, `BMC_VirtualSystemEnabler` is related to the host system with the appropriate `EnablerType` attribute is set to the correct type of software (for example, LDOM Hypervisor) and relationships are set to `BMC_ComputerSystem` (the physical computer).

For containers, create a relationship to `BMC_VirtualSystemEnabler` (Solaris Resource Manager) and relationships to the domain (or physical computer, depending on the configuration), and operating system.

## Logical identity of BMC\_ResourcePool for virtual systems

The BMC\_ResourcePool class serves as a logical entity (with associated controls) provided by the host system to allocate and assign resources. A resource pool may be used to allocate resources of a specific type. Hierarchies of resource pools may be created to provide administrative control over allocations. In cases where resources are subdivided, multiple resource pools may exist.

Key attributes for defining resource pools using the BMC\_ResourcePool class are described in Table 1-9.

**Table 1-9: Key attributes for BMC\_ResourcePool**

Attribute	Usage
Primordial	<p>Specifies how the ResourcePool is used in the activity of resource management. If set to true, this attribute indicates that the ResourcePool is a base from which resources are drawn and returned in the activity of resource management. It also indicates that this ResourcePool shall not be created or deleted by consumers of this model. However, other actions (whether they are modeled or not), may affect the characteristics or size of primordial ResourcePools. If set to false (the default), this attribute indicates that the ResourcePool serves as a concrete Resource Pool, meaning that is subject to resource allocation services functions.</p> <p>This distinction is important, because higher-level ResourcePools may be assembled using the Component or ElementAllocatedFromPool associations. Although the higher-level abstractions can be created and deleted, the most basic, hardware-based ResourcePools (such as primordial pools) cannot. Instead, they are physically realized as part of the system, or are actually managed by some other system and imported as if they were physically realized.</p>
ResourceType	<p>Specifies the type of resource that the resource pool may allocate. Values are Other (0), Computer System (2), Processor (3), Memory (4), IDE Controller (5), Parallel SCSI HBA (6), FC HBA (7), iSCSI HBA (8), IB HCA (9), Ethernet Adapter (10), Other Network Adapter (11), I/O Slot (12), I/O Device (13), Floppy Drive (14), CD Drive (15), DVD drive (16), Disk Drive (17), Tape Drive (18), Storage Extent (19), Other storage device (20), Serial port (21), Parallel port (22), USB Controller (23), Graphics controller (24), IEEE 1394 Controller (25), Partitionable Unit (26), Base Partitionable Unit (27), Power (28), Cooling Capacity (29), Ethernet Switch Port (30), Logical Disk (31), Storage Volume (32), Ethernet Connection (33).</p>

In systems that support over-commitment, pools represent the reservable capacity, not an upper bound or limit on the maximum amount that can be allocated. Admission control during power-on may detect and prevent systems from powering due to resource exhaustion. For example, over-commitment on a resource pool with `ResourceType` set to Memory would require that sufficient space be available in a backing store that might be managed through a storage resource pool. Figure 1-7 on page 34 illustrates an example virtual system model including resource pools.

## Logical identity of BMC\_ResourceAllocationSettingData for virtual systems

The `BMC_ResourceAllocationSettingData` class (derived from `BMC_Settings`) represents settings that specifically relate to an allocated resource.

Use `BMC_VirtualSystemSettingData` and `BMC_ResourceAllocationSettingData` to represent virtual system settings, and `BMC_ResourcePool` to model resource pools. Figure 1-7 illustrates an example virtual system model including settings

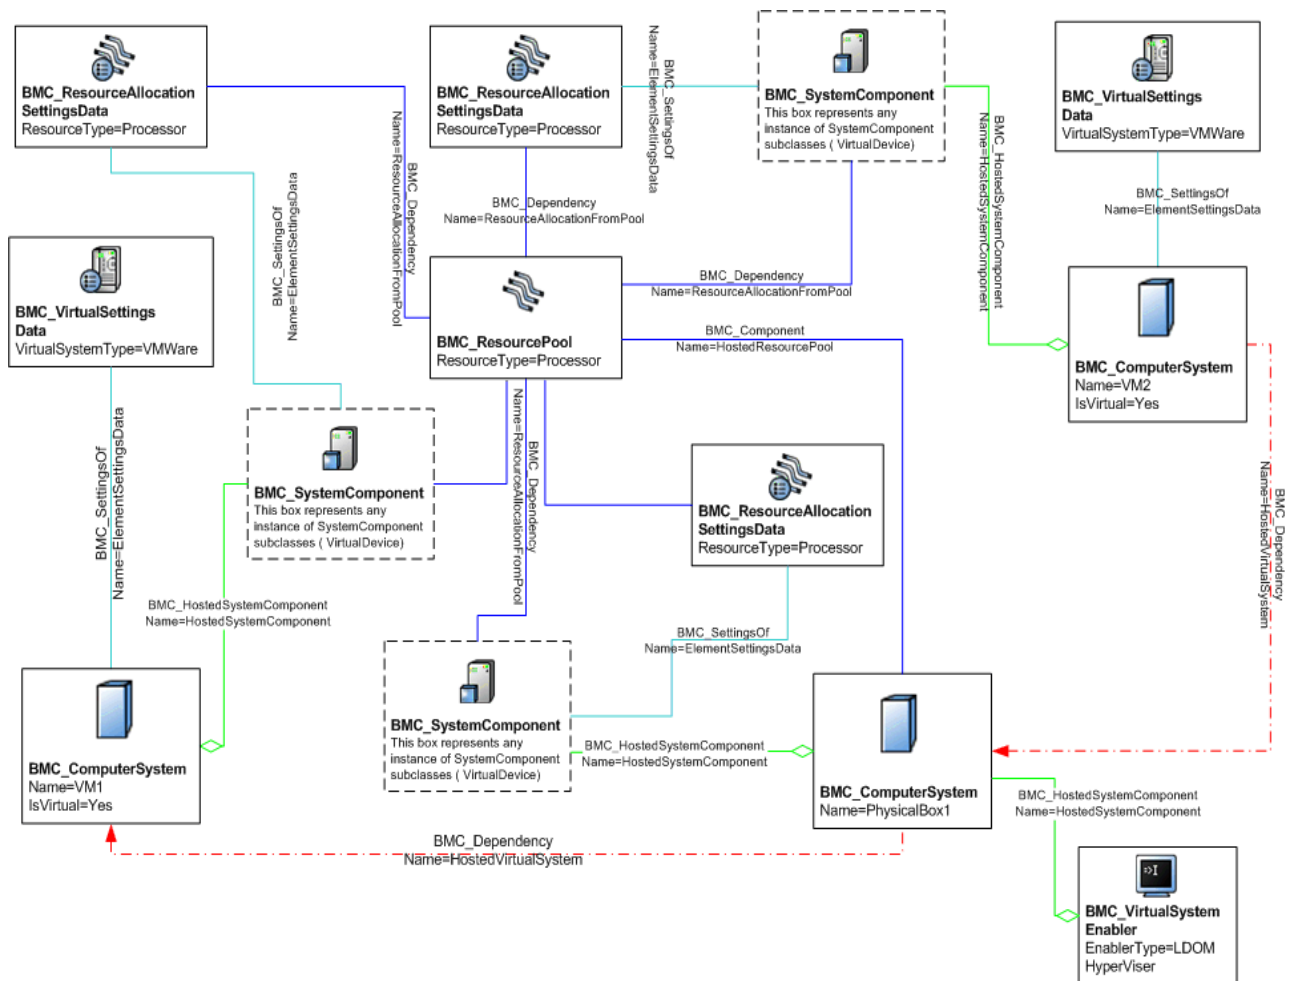

The key attribute for defining settings using the `BMC_ResourceAllocationSettingData` class is `ResourceType`, described in Table 1-10.

**Table 1-10: Key attribute for ResourceAllocationSettingData**

Attribute	Usage
<code>ResourceType</code>	Specifies the type of resource that this allocation setting represents. Values are Other (0), Computer System (2), Processor (3), Memory (4), IDE Controller (5), Parallel SCSI HBA (6), FC HBA (7), iSCSI HBA (8), IB HCA (9), Ethernet Adapter (10), Other Network Adapter (11), I/O Slot (12), I/O Device (13), Floppy Drive (14), CD Drive (15), DVD drive (16), Disk Drive (17), Tape Drive (18), Storage Extent (19), Other storage device (20), Serial port (21), Parallel port (22), USB Controller (23), Graphics controller (24), IEEE 1394 Controller (25), Partitionable Unit (26), Base Partitionable Unit (27), Power (28), Cooling Capacity (29), Ethernet Switch Port (30).

**Figure 1-7: Model of a virtual system with one resource pool and resource allocation**

Using Figure 1-7 as an example, a physical box is related to BMC\_ResourcePool by BMC\_Component where the Name attribute is set to HostedResourcePool. Use the relationship class BMC\_MemberOfCollection, where the Name attribute is set to isMemberofPool to allocate resources and resource pools. You can use the relationship class BMC\_Dependency, where the Name attribute is set to ElementAllocatedFromPool to allocate resources and resource pools. You can also use the relationship class BMC\_Dependency, where the Name attribute is set to ResourceAllocationFromPool to allocate resources and resource pools.

## Deprecated classes for virtual systems

The following classes were deprecated in BMC Atrium CMDB 7.5.00, and are no longer used for modeling virtualized environments:

- BMC\_VirtualSystem (including all subclasses)
- BMC\_VMWare
- BMC\_VMWareVirtualSystem

- BMC\_UnixVirtualSystem
- BMC\_MFVirtualSystem
- BMC\_MFVirtualSystemEnabler
- BMC\_LPAR

## Relationships used for virtual systems

Table 1-11 describes the relationships for virtual systems.

**Table 1-11: Relationships used for virtual systems**

Relationship	Relationship class	Value of Name attribute
Managed elements and setting data	BMC_SettingsOf	ELEMENTSETTINGDATA
Allocated resource and resource pool	BMC_MemberOfCollection	ISMEMBEROFPPOOL
Resource allocated from a pool	BMC_Dependency	ELEMENTALLOCATEDFROMPOOL

## Operating system modeling

An operating system is software or firmware that controls the operation of a computer and directs the processing of programs. This section describes how to model Windows and UNIX operating systems.

To model a Windows or UNIX operating system, create an instance of the `BMC_OperatingSystem` class. Associate the instance to the parent `BMC_ComputerSystem` instance by a `BMC_HostedSystemComponents` relationship.

### NOTE

This class is not reserved for servers and workstations only but is used to capture any type of operating system, such as the IOS for a Cisco network switch or router.

## Logical identity of BMC\_OperatingSystem

As with any related component of BMC\_ComputerSystem, an operating system is identified by the Name attribute in conjunction with the SystemName attribute that represents the name of the parent instance of the computer. Therefore, the Name attribute represents the local name of the operating system CI in the context of the computer that is hosting it, as described in Table 1-13.

**Table 1-12: Key attributes for BMC\_OperatingSystem**

Attribute	Usage
Name	Identifies the name of the child instance in the context of the parent instance of BMC_ComputerSystem.  If multiple operating systems are installed on the same computer, Name must be structured so that the multiple instances have different names.
SystemName	Specifies the name of the system. This must be the same as the parent instance of the BMC_ComputerSystem Name attribute. This attribute is automatically populated from the related CI when a weak relationship is created between the operating system and a computer system.

## Additional attributes for BMC\_OperatingSystem

Table 1-14 describes additional attributes of BMC\_OperatingSystem.

**Table 1-13: Additional attributes of BMC\_OperatingSystem**

Attribute	Usage
Description	The description for the operating system.
ManufacturerName	The company that manufactured the operating system.
SerialNumber	The serial number of the operating system.
ShortDescription	A caption for the operating system.
VersionNumber	The version number of the operating system.

## Hardware component modeling

The hardware components that make up a computer system are captured by subclasses of BMC\_HardwareSystemComponent. Generally, one subclass represents one type of hardware component. Examples of hardware components include:

- Disk drive—Machine that reads data from and writes data to a disk.
- Disk partition—Logical allocation of space on a disk drive.
- Monitor—Video device attached to computer systems that displays computer operations.
- Keyboard—Set of typewriter-like keys that enables you to enter data into a computer.
- Memory—Stores information about internal storage areas in a computer.

- Processor—Device that interprets a machine instructions in a computer.
- Network port—Interfaces that connect network drives to computer systems.

For example, you might identify a specific processor as an instance of `BMC_HardwareSystemComponent`. Each instance representing a hardware component is associated to the parent `BMC_ComputerSystem` instance by the `BMC_HostedSystemComponents` relationship.

## Logical identity of `BMC_HardwareSystemComponent`

Like any child instance of `BMC_ComputerSystem`, a hardware component is identified by the `Name` attribute in conjunction with the `SystemName` attribute that represents the name of the parent computer instance. Therefore, the `Name` attribute represents the local name of the hardware CI in the context of the computer that is hosting it, as described in Table 1-15.

**Table 1-14: Key attributes for `BMC_HardwareSystemComponent`**

Attribute	Usage
<code>Name</code>	Identifies the child instance in the context of the parent instance of <code>BMC_ComputerSystem</code> .
<code>SystemName</code>	Specifies the name of the system. This must be the same as the parent instance of <code>BMC_ComputerSystem</code> <code>Name</code> attribute. This attribute is automatically populated from the related CI when a weak relationship is created between the computer system and the operating system.

## Additional attributes for `BMC_HardwareSystemComponent`

Table 1-16 describes additional attributes of `BMC_HardwareSystemComponent`.

**Table 1-15: Additional attributes of `BMC_HardwareSystemComponent`**

Attribute	Description
<code>Description</code>	The description for the component.
<code>ManufacturerName</code>	The company that manufactured the component.
<code>SerialNumber</code>	The serial number of the component.
<code>ShortDescription</code>	A caption for the component.
<code>VersionNumber</code>	The version number of the component.

Because each hardware component contains attributes specific to its type, see the BMC Atrium CMDB 7.6.04 Data Model Help for a complete list of `BMC_HardwareSystemComponent` types and attributes to ensure you can accurately and completely represent your specific hardware CIs.

## Access point modeling

A computer provides functions for other entities to use. Access points represent those available functions. Each access point represents the configuration of access to a function or the ability to invoke a service and is modeled by the `BMC_AccessPoint` class. This characteristic is further defined by `BMC_ProtocolEndpoint`, the only direct subclass of `BMC_AccessPoint`. Among other types of access points, a network address such as an IP address, MAC address, or IPX address, is captured as a subclass of `BMC_AccessPoint`.

Instances of the `BMC_AccessPoint` class are related to a computer system through a `BMC_HostedAccessPoint` dependency relationship. Access points exist within the context of a computer system, and are associated to their parent instance of the system through the `BMC_HostedAccessPoint` dependency relationship.

For example, Figure 1-4 on page 25 illustrates an example of a computer system's relationship to an IP endpoint, in the context of modeling a router.

### Logical identity of `BMC_IPEndpoint`

An IP address is modeled as an instance of `BMC_IPEndpoint`. Like any child instance of `BMC_ComputerSystem`, an instance of `BMC_IPEndpoint` is identified by the `Name` attribute in conjunction with the `SystemName` attribute that represents the name of the parent instance of the computer. Therefore, the `Name` attribute represents the local name of the CI in the context of the computer that is hosting it, as described in Table 1-17.

**Table 1-16: Key attributes for `BMC_IPEndpoint`**

Attribute	Usage
Name	Identifies the child instance in the context of the parent instance of the <code>BMC_ComputerSystem</code> . Name must be an IPv4 or IPv6 address, and must be formatted as decimal numbers delimited by a period, with no leading zeros.
NameFormat	Sets the heuristic used to generate the Name value. This value must be set to IP.
SystemName	Specifies the name of the system. This must be the same as the parent instance of the <code>BMC_ComputerSystem</code> Name attribute. This attribute is automatically populated from the related CI when a weak relationship is created between the computer system and the operating system.

## Additional attributes for BMC\_IPEndpoint

Table 1-18 describes additional attributes of BMC\_IPEndpoint.

**Table 1-17: Additional attributes of BMC\_IPEndpoint**

Attribute	Description
Address	The IP address. This value must be compliant with AddressType.
AddressType	The enumeration that defines the type of address. This value must be set to either 0 (Unknown), 1 (IPv4), or 2 (IPv6).
DNSName	The system name based on its DNS name. The DNS name corresponds to the IP address; therefore, when you want to search a system by DNS name, you should look up the IPEndpoint CIs, and then the parent computer.
ProtocolType	The enumeration that categorizes and classifies instances of this class.
ShortDescription	A caption of the IP address.
SubnetMask	The IP address subnet mask.
ManagementAddress	The selection that defines if the IP address is a management address such as a Discovered Address or an SNMP address.

## Logical identity of BMC\_LANEndpoint

A MAC address is modeled as an instance of BMC\_LANEndpoint. Like any child instance of BMC\_ComputerSystem, a MAC address is identified by the Name attribute in conjunction with the SystemName attribute that represents the name of the parent instance of the computer. Therefore, the Name attribute represents the local name of the CI in the context of the computer that is hosting it, as described in Table 1-19.

**Table 1-18: Key attributes for BMC\_LANEndpoint**

Attribute	Usage
Name	Identifies the MAC address. The value must be an address suffixed by an index. The index uniquely identifies a MAC address for situations where multiple identical MAC addresses are configured within the same system. The index is generally the index of the MAC address entry in the SNMP MIB.
NameFormat	Specifies the heuristic used to generate the Name value. This value must be set to MACAddress:Index.
SystemName	Specifies the name of the system. This must be the same as the parent instance of the BMC_ComputerSystem Name attribute. This attribute is automatically populated from the related CI when a weak relationship is created between the computer system and the operating system.

## Additional attributes of BMC\_LANEndpoint

Table 1-20 describes additional attributes of BMC\_LANEndpoint.

**Table 1-19: Additional attributes of BMC\_LANEndpoint**

Attribute	Description
Address	The MAC address.
ProtocolType	The enumeration that categorizes and classifies instances of this class, such as for 14 (for Ethernet).
ShortDescription	A caption of the MAC address.

## Access point binding

Some access points use the services provided through another access point. You can use access point binding to establish a layering of two protocols, with the upper layer represented by the dependent and the lower layer represented by the antecedent.

This binding is modeled in the CDM by the BMC\_Dependency relationship with the Name attribute set to BindsTo.

## Network interface and address modeling

Network interfaces are captured by instances of BMC\_NetworkPort. Although model extensions might define subclasses (like a FiberChannel port), the class that you should use for network interfaces is BMC\_NetworkPort. Like other hardware components, each instance of a network port is associated to the parent instance of the BMC\_ComputerSystem by the BMC\_HostedSystemComponents relationship.

Network addresses are captured by BMC Discovery products as access points (inherited from BMC\_AccessPoint) and therefore must always be associated to their parent instance of the computer through the BMC\_HostedAccessPoint relationship. Also, a network address can have a relationship to the network interface for which it is configured. This relationship is modeled by a BMC\_Dependency relationship in which the network interface is the antecedent (source) and the network address is the dependent (destination).

For more information on modeling network addresses, including an illustration of the relationships used in the model, see Chapter 5, “Network topology modeling.”.

## Logical identity of BMC\_NetworkPort

Like any child instance of `BMC_ComputerSystem`, a network port is identified by the `Name` attribute in conjunction with the `SystemName` attribute that represents the name of the parent instance of the computer. Therefore, the `Name` attribute represents the local name of the CI in the context of the computer that is hosting it, as described in Table 1-21.

**Table 1-20: Key attributes for BMC\_NetworkPort**

Attribute	Usage
Name	Identifies the network address. This must be an address suffixed by an index. The index uniquely identifies a MAC address for situations where multiple identical MAC addresses are configured within the same system.  The index is generally the index of the MAC address entry in the SNMP MIB.
NameFormat	Specifies the heuristic used to generate the Name value. For instance, in many cases, network interfaces are best discovered and identified using SNMP information.
PhysicalIndex	Specifies the index, which must be a valid SNMP index relative to the SNMP IF Table of the computer.
SystemName	Identifies the name of the system. This must be the same as the parent instance of the <code>BMC_ComputerSystem</code> <code>Name</code> attribute. This attribute is automatically populated from the related CI when a weak relationship is created between the computer system and the operating system.

## Additional attributes for BMC\_NetworkPort

Table 1-22 describes additional attributes of `BMC_NetworkPort`.

**Table 1-21: Additional attributes for BMC\_NetworkPort (Sheet 1 of 2)**

Attribute	Description
AutoSense	The Boolean value that indicates whether the port can automatically determine the speed or other communications characteristics of the connected network media.
Description	The description for the component.
FullDuplex	The Boolean value that indicates whether the port is operating in full duplex mode (carrying signals in both directions).
LinkTechnology	The enumeration of the types of link technologies, with values such as Unknown, Other, Ethernet, IB, FC, FDDI, ATM, Token Ring, Frame Relay, Infrared, BlueTooth, or Wireless LAN.
ManufacturerName	The company that manufactured the component.
MaxSpeed	The maximum bandwidth of the port in bits/second.
NetworkAddresses	The list of strings specifying the network addresses for the port.

**Table 1-21: Additional attributes for BMC\_NetworkPort (Sheet 2 of 2)**

Attribute	Description
PermanentAddress	The network address hard-coded into the port. This address can be changed by a firmware upgrade or software reconfiguration. If it is changed, update this field. If no hard-coded address exists for the network port, leave this attribute blank.
PhysicalDescription	The physical description or location for the port, such as slot3/port4.
PortType	The enumeration of the types of ports, with values such as Ethernet, FDDI, Token Ring, WAN, or Unknown.
ShortDescription	A caption for the component.
SerialNumber	The serial number of the component.
SpeedConfigured	The maximum bandwidth of the port in bits/second.

# Software and hardware cluster modeling

Use the `BMC_Cluster` class to classify or update groups of software or hardware. Clusters are modeled using the `BMC_Cluster` class, which stores information about the cluster in relation to the `BMC_System` component.

Clusters help increase the performance of resources by storing groups of two or more computer systems or applications so that they operate together as a functional whole. Using clusters helps to improve and maintain the reliability, serviceability, and availability of your operating-system environment.

For example, an accounting department might create a cluster and link it with relationships to specific computer systems to obtain a complete picture of their business environment and assess the performance of computers individually and collectively.

# 2 Application modeling

This section describes how to model software business entities, including applications, software servers, databases, and middleware.

The following topics are provided:

- Application characteristics (page 44)
- Application infrastructure and hosting environment (page 47)
- Relationships for applications (page 48)
- Business applications and services (page 49)

# Application characteristics

Applications have characteristics that help you determine how to best use the CDM in your modeling strategy. Table 2-1 maps the characteristics of an application to the type of class you would use to model that application. Note that not all objects and relationships are required to model certain types of applications. For example, patch information may not be required in the case of software license management.

**Table 2-1: Mapping application characteristics to a class**

Characteristic	Description	Class
Runtime aspect	Running instances of applications and software servers	BMC_SoftwareServer BMC_Application BMC_ApplicationInfrastructure
Installation aspect	Identifies the product that is installed, its version, and any patch	BMC_Product
Service aspect	Business applications. (For business applications supporting a particular function such as payroll and trading, use the BMC_BusinessService class.)	BMC_Application BMC_BusinessService

Figure 2-1 on page 47 illustrates how the installed, runtime, and service aspects of an application relate to each other.

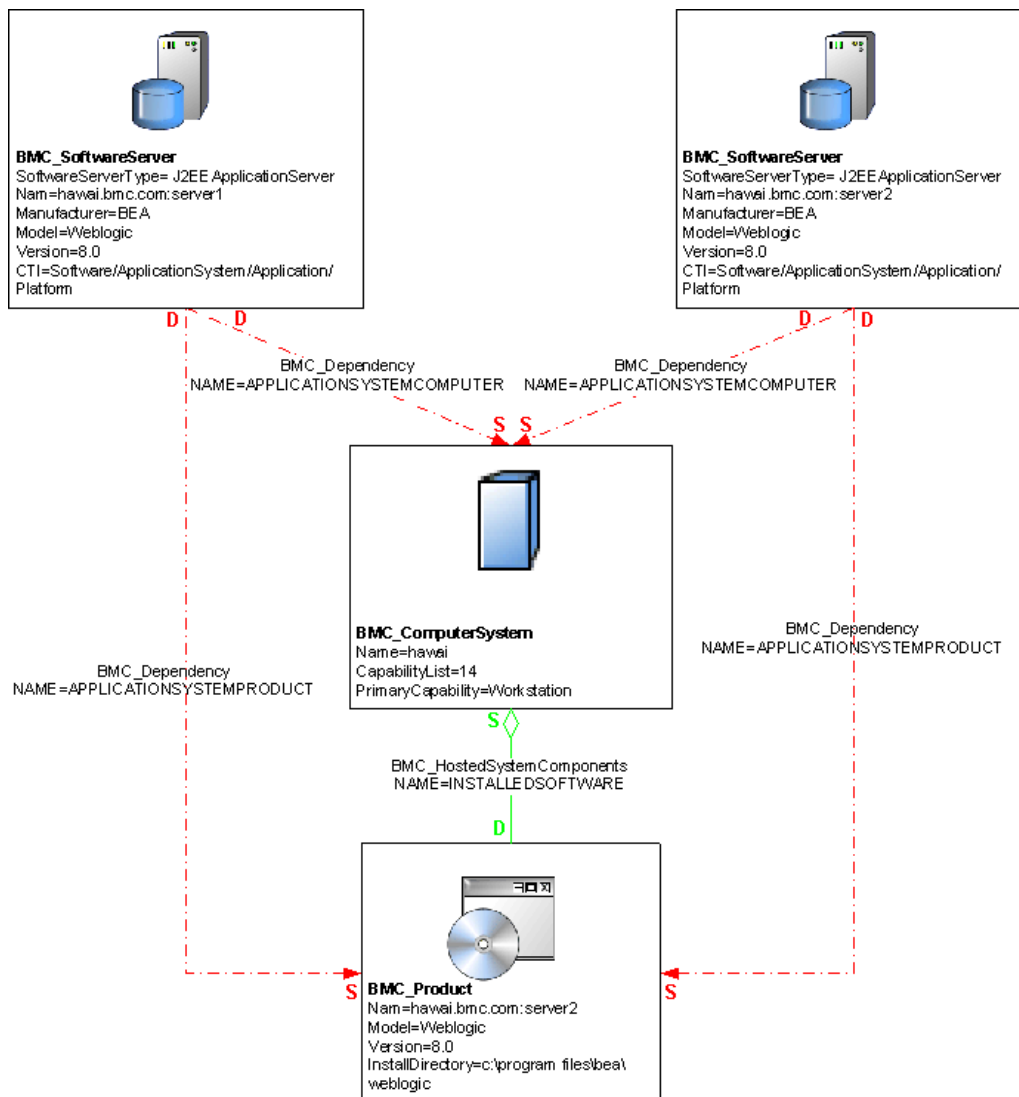

\_\_\_\_\_

You can also use the `BMC_Product` class to model noncommercial products, such

As another example, you would model Weblogic first by instantiating the

Figure 2-2 illustrates an example of this model, where two instances of a Weblogic application server (server1 and server2) are actually instances of the same installed product.

**Figure 2-2: Illustrative model of a Weblogic application**

Accounting for the runtime aspect of the application in this context is very important for understanding the impact of an application on a business service. You must consider capturing Weblogic patches (using the `BMC_Patch` class), because the patch will then be connected to the service through the installed product, runtime, applications and, ultimately, the service and its relationships. Consequently, an IT administrator responsible for updating patches on Weblogic would understand how the change relates to the business that Weblogic supports.

For complete descriptions of the classes described in this section for modeling applications, including examples of usage, see the BMC Atrium CMDB 7.6.04 Data Model Help. For more information about using the `BMC_Product` class to model components, see “Software inventory and patch modeling” on page 22.

# Application infrastructure and hosting environment

The `BMC_Application` class stores information about standalone applications, applications deployed on servers (such as SAP), and applications deployed on distributed systems (such as SAP).

The `BMC_ApplicationInfrastructure` class stores information about the framework that supports applications in a distributed or composite system. This class represents the platform to model your applications. For example, you would model SAP® as an instance of `BMC_ApplicationInfrastructure`. After an application is deployed in that platform, it can run on any application server in the SAP environment. An application can be hosted by different types of environments: an application server or application system, or a physical or virtual system.

## Applications running on application servers or application systems

To model applications to run directly on top of an application server or application system, relate an instance of the `BMC_Application` class to a hosting `BMC_ApplicationInfrastructure` instance. In this model, the application has only one relationship: a dependency on the application infrastructure hosting the application. This dependency is modeled by a `BMC_Dependency` relationship, as illustrated in Figure 2-3. When using the relationship, set the `Name` value to `DEPLOYEDAPPLICATION`.

**Figure 2-3: Illustrative model of applications running on application systems**

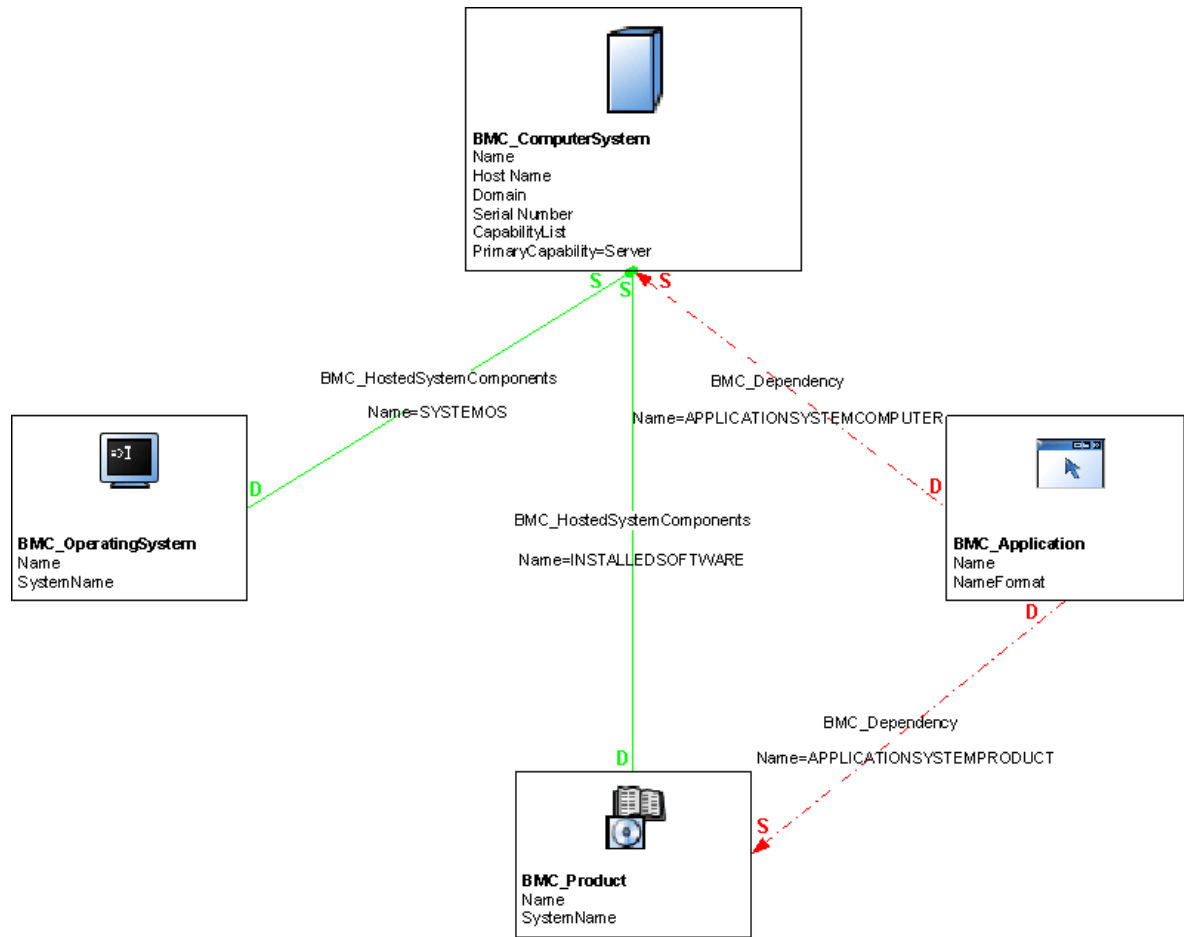

An application infrastructure cannot have any direct relationship to computers. Only applications and software servers have relationships to computers.

This model can also be applied to an application or set of applications that support or collaborate to provide a particular business function. For example, an Oracle® application infrastructure supports two applications, TimeCard and HR personal data, both stored in the `BMC_Application` class. The two classes relate to each other through the `BMC_Dependency` relationship, meaning that both the TimeCard and HR personal data applications are dependent on the supporting Oracle application infrastructure. To decompose the system into its functional components, relate an instance of this class to its component `BMC_SoftwareServer` instance with the `BMC_Dependency` class.

## Applications running on computer systems

To model applications to run on computer systems (physical or virtual), relate an instance of the BMC\_Application class to a hosting physical or virtual BMC\_ComputerSystem instance. Figure 2-4 illustrates this model.

Figure 2-4: Illustrative model of applications running on computer systems

## Relationships for applications

The relationships for modeling applications are described in Table 2-2.

Table 2-2: Relationships for modeling applications

Relationship	Relationship class	Value of Name attribute
Application infrastructure hosting the application.	BMC_Dependency	DEPLOYEDAPPLICATION
System hosting the application (mandatory).	BMC_Dependency	APPLICATIONSYSTEMCOMPUTER

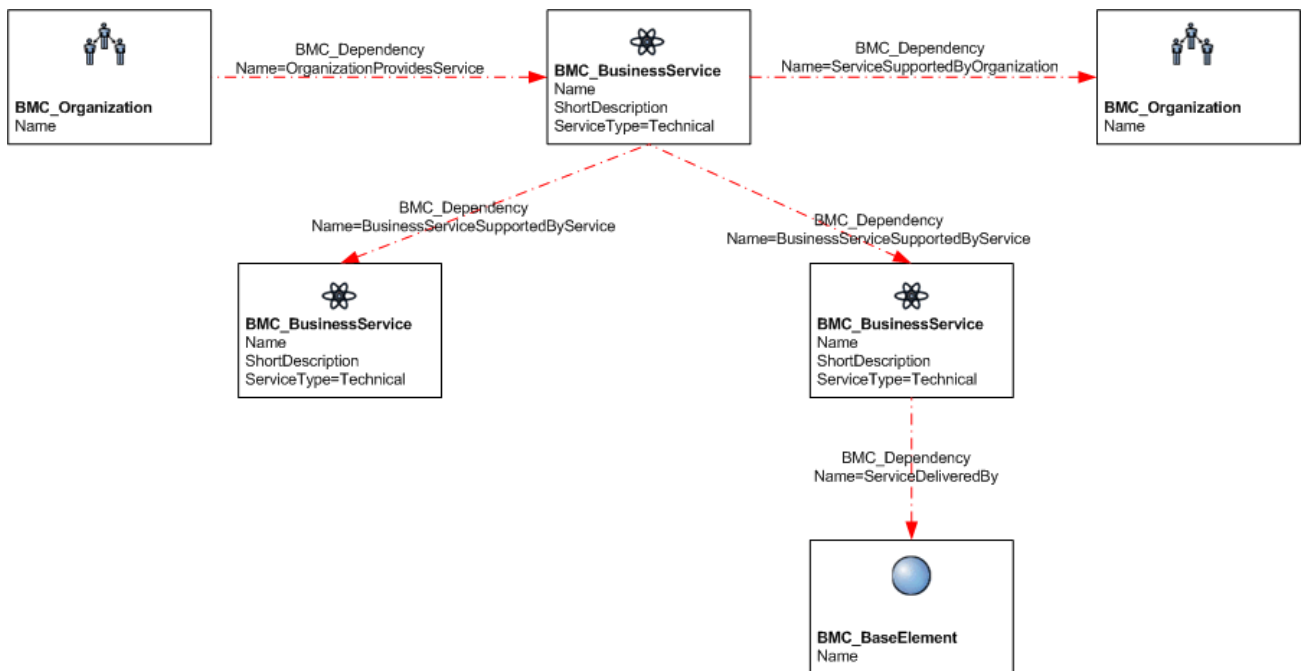

**Table 2-2: Relationships for modeling applications (Continued)**

Relationship	Relationship class	Value of Name attribute
Operating system running the application (optional).	BMC_Dependency	APPLICATIONSYSTEMOS
Product representing the installed software of which this application is an instance (optional).	BMC_Dependency	APPLICATIONSYSTEMPRODUCT

## Business applications and services

To model the business aspect of applications, use the `BMC_BusinessService` class. Business applications support a particular business function (such as payroll or trading) and are, generally, made up of a set of applications, servers, and databases that collaborate to provide a particular service.

**Figure 2-5: Illustrative model of business services**

### NOTE

In this model, the `BMC_BaseElement` Name is typically an application or database.

# Software server modeling

This section describes how to model software servers, such as database servers, web servers, DNS servers, mainframe servers, and directory servers.

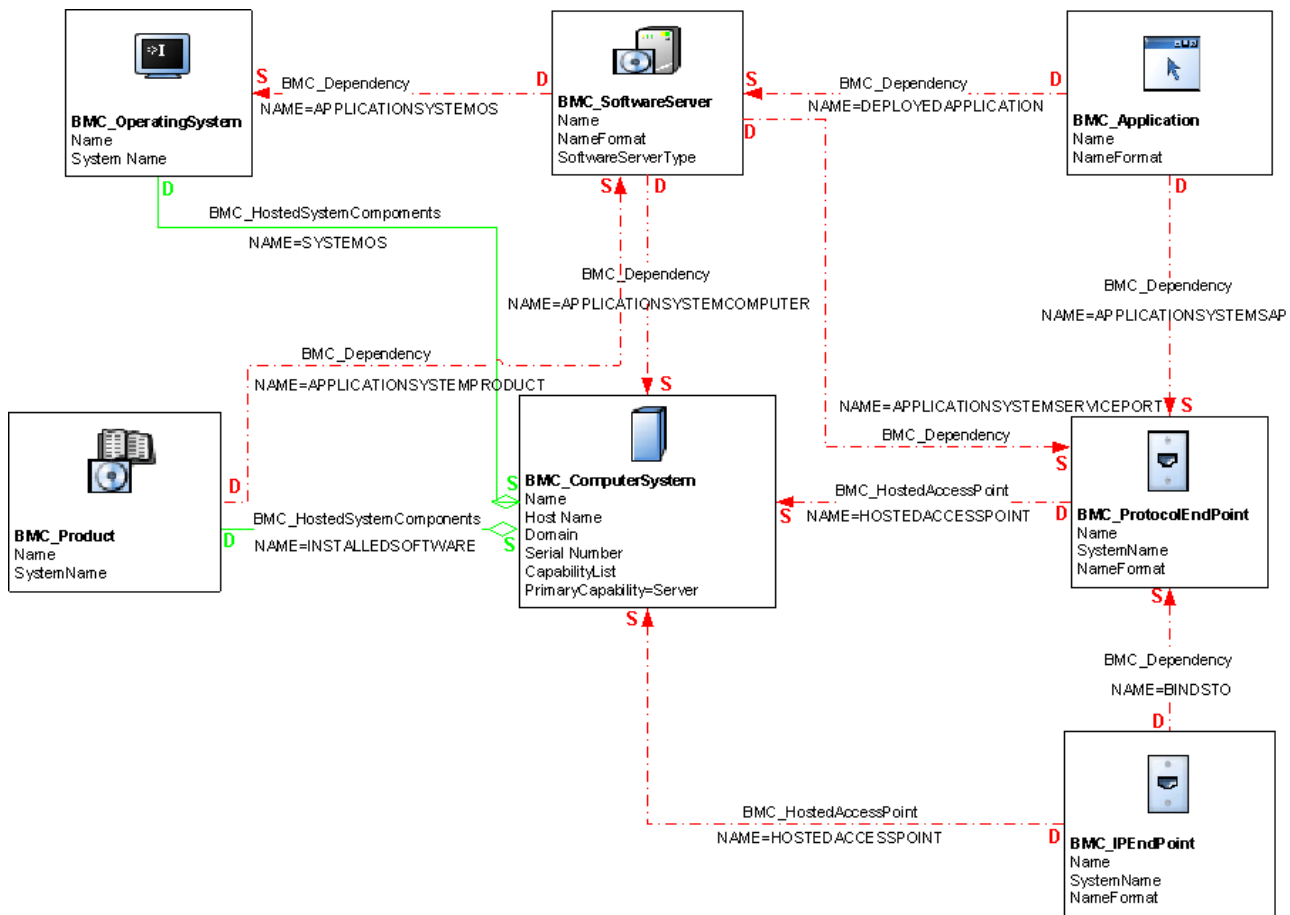

The following topics are provided:

- Software server characteristics (page 52)
- Logical identity of BMC\_SoftwareServer (page 52)
- Database server modeling (page 54)
- Relationships for database servers and databases (page 57)
- Database storage entity modeling (page 58)

# Software server characteristics

A software server is a system that provides services to client applications and other servers, runs on top of a physical or virtual system, and is modeled using the BMC\_SoftwareServer class. Figure 3-1 illustrates a software server model.

Figure 3-1: Illustrative model of software servers

## Logical identity of BMC\_SoftwareServer

The BMC\_SoftwareServer class stores information about a server that provides a single service to client applications or other systems. Database servers, web servers, DNS servers, mainframe servers, and directory servers can be represented by this class.

Table 3-1 details the key attributes used in the BMC\_SoftwareServer class. When modeling software servers, you identify the unique server type by specifying its name in the SoftwareServerType attribute.

For example, for database servers, set the `SoftwareServerType` attribute to `DatabaseServer`.

**Table 3-1: Key attributes for BMC\_SoftwareServer**

Attribute	Usage
Name	Identifies the name of the software server.
NameFormat	Sets the heuristic used to generate the Name value. Set this attribute to name the installation directory of the server.
SoftwareServerType	Specifies the type of software server (for example, <code>DatabaseServer</code> ).

## Additional attributes for BMC\_SoftwareServer

Table 3-2 describes additional attributes for `BMC_SoftwareServer`.

**Table 3-2: Additional attributes for BMC\_SoftwareServer**

Attribute	Description
ShortDescription	A caption of the software server.
TokenId	The unique identifier populated by BMC Discovery products and used by the Reconciliation Engine (of BMC Atrium CMDB) to identify instances.

## Relationships for software servers

Table 3-3 describes the relationships for software servers.

**Table 3-3: Relationships for software servers**

Relationship	Relationship class	Value of Name attribute
Computer system hosting the software server (mandatory).	BMC_Dependency	APPLICATIONSYSTEMCOMPUTER
Communication endpoint (one relationship per endpoint) that the software server is listening on.	BMC_Dependency	APPLICATIONSYSTEMSERVICEENDPOINT
Operating system running the application. This dependency is actually on the OS that is running the server (as opposed to the computer).	BMC_Dependency	APPLICATIONSYSTEMOS
Installed software of which this software server is an instance (optional).	BMC_Dependency	APPLICATIONSYSTEMPRODUCT

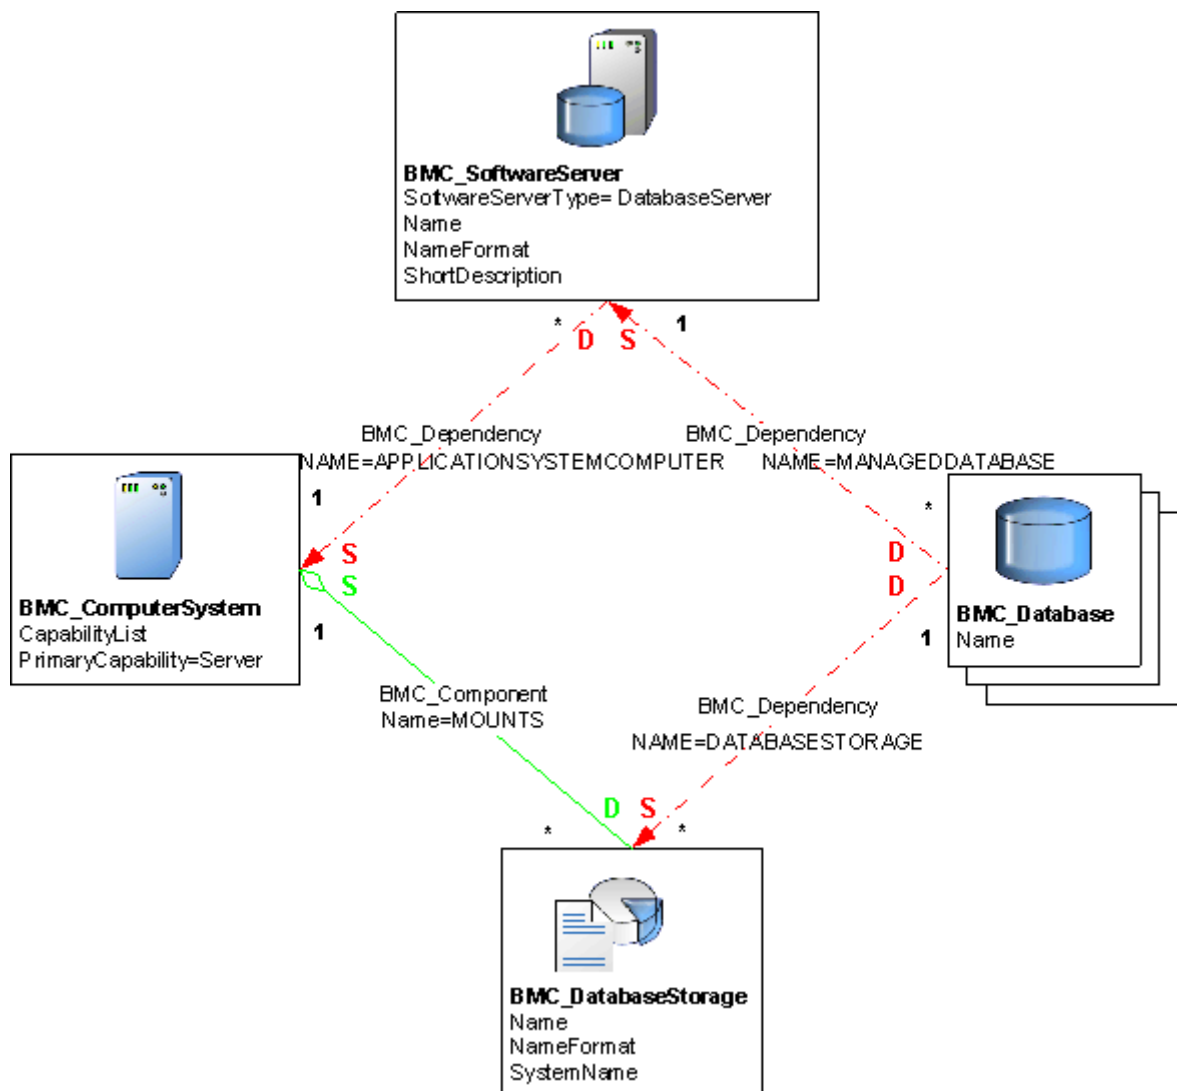

# Database server modeling

A database server is a form of software server that, like all software servers, must be uniquely named in the context of the CDM. A database server is modeled as an instance of the `BMC_SoftwareServer` class (derived from the `BMC_ApplicationSystem` class) and is identified by its `Name` attribute.

The key attribute for this class is `SoftwareServerType`, which must be set to `DatabaseServer`.

Figure 3-2 illustrates how to model a database server.

**Figure 3-2: Illustrative model of a database server environment**

## Database modeling

A database is a collection of interrelated data that is treated as a unit and that is organized into one or more schemas. Databases are dependent on software servers and, therefore, are dependent on database servers.

### Logical identity of BMC\_DataBase

A database is modeled as an instance of the `BMC_DataBase` class (derived from the `BMC_LogicalEntity` class) and is identified by its `Name` attribute.

Table 3-4 describes the description and syntax for the `Name` and `NameFormat` attributes used in the `BMC_DataBase` class.

**Table 3-4: Key attributes for BMC\_DataBase**

Attribute	Usage
<code>Name</code>	Identifies the database.
<code>NameFormat</code>	<p>As multiple valid naming conventions can be used in specific contexts, the <code>NameFormat</code> attribute must be set with a value indicating the heuristic used to generate the <code>Name</code> value. For example, in some cases, a computer system will be identified by an external DNS Name (a name configured in a DNS Server). In other cases, a static IP Address will be used. In any case, the values for <code>NameFormat</code> should be:</p> <ul style="list-style-type: none"> <li>■ <code>HostName.IP</code>: The name must be a valid IP Address, decimal bytes delimited with dots ('.')</li> <li>■ <code>HostName.DNS</code>: The name must a fully qualified host name, a host name and a domain name delimited with dots (the domain name can also consist of multiple components delimited with dots).</li> </ul>

The `BMC_DataBase` class defines the properties that are common across database models and vendor implementations for the database entity that is represented by the unit of interrelated data. Create an instance of this class for each managed database. You can use this class to specify the software that belongs to the database, perform system-wide database management operations (such as stopping all the databases that were created by the system for maintenance purposes), or view runtime statistics for the database.

To represent database storage areas, use the `BMC_DataBaseStorage` class. The key to a `BMC_DataBase` instance in an enterprise environment is its `Name` attribute. For more information about database storage, see “Database storage entity modeling” on page 58.

## Additional attributes for BMC\_DataBase

Although databases are primarily defined by the `Name` attribute, Table 3-5 provide additional information about an instance of `BMC_DataBase`:

**Table 3-5: Additional information for BMC\_DataBase**

Attribute	Description
ShortDescription	A short description of the database.
TokenId	A unique identifier populated by BMC Discovery products and used by the Reconciliation Engine (of BMC Atrium CMDB) to identify instances.

## Oracle Listener modeling

The Oracle Listener manages network communications for one or more database instances. An Oracle Listener is modeled as an instance of the `BMC_SoftwareServer` class (derived from `BMC_ApplicationSystem`) and is identified by both its `Name` attribute (set to Oracle Listener) and `SoftwareServerType` attribute (set to Other).

Table 3-6 details the attributes used to model Oracle Listeners.

**Table 3-6: Attributes used to model Oracle Listeners**

Attribute	Usage
Name	Identifies the Oracle Listener.
NameFormat	Defines the heuristic used to generate the <code>Name</code> value.
SoftwareServerType	Defines the type of server. This value must be set to Other.
ShortDescription	A caption of the database.
TokenId	Specifies the unique identifier populated by BMC Discovery products and used by the Reconciliation Engine to identify instances.

# Relationships for database servers and databases

The BMC\_Dependency class is a generic association used to establish dependency relationships between instances in the BMC Atrium CMDB. This association allows you to establish dependency relationships between endpoints, including the roles of the endpoints.

Table 3-7 describes the relationships for database servers and databases.

**Table 3-7: Relationships for database servers and databases**

Relationship	Relationship class	Value of Name attribute
Computer system (source) and database server (destination)	BMC_Dependency	APPLICATIONSYSTEMCOMPUTER
Computer system (source) and Oracle Listener (destination)	BMC_Dependency	APPLICATIONSYSTEMCOMPUTER
Oracle Listener (source) and database server (destination)	BMC_Dependency	DEPENDENCY
Installed software of which this software server is an instance (optional).	BMC_Dependency	APPLICATIONSYSTEMPRODUCT
Database server (source) and database (destination)	BMC_Dependency	MANAGEDDATABASE
Computer system (source) and the file system (destination)	BMC_HostedSystemComponents	HOSTEDSYSTEMCOMPONENT
Database storage (source) and database (destination)	BMC_Component	DATABASEDATASTORAGE

# Database storage entity modeling

Database storage entities are an extension of file system CIs in a database environment and are modeled using the `BMC_DataBaseStorage` class.

## Logical identity of `BMC_DataBaseStorage`

The `BMC_DataBaseStorage` class stores information about a collection of logical storage areas that hold and retain data. You model a database storage CI as an instance of the `BMC_DataBaseStorage` class (derived from the `BMC_FileSystem` class) and identify the instance by its `Name` and `SystemName` attributes. The `BMC_DataBaseStorage` class extends a file system CI and uses its inherited associations to represent the internal structure of the database.

Table 3-8 details the attributes used to model database storage CIs.

**Table 3-8: Key attributes for model database storage CIs**

Attribute	Usage
Name	Identifies the storage area (tablespace) name.
NameFormat	Specifies the heuristic used to generate the Name value. Set it with the storage name used to generate the Name value.
SystemName	Specifies the name of the parent BMC_Database CI. This attribute is automatically populated from the related CI when a weak relationship is created between the computer system and the operating system.

## Additional attributes for `BMC_DataBaseStorage`

Table 3-9 describes attributes that provide additional information about an instance of `BMC_DataBaseStorage`.

**Table 3-9: Additional information for `BMC_DataBaseStorage`**

Attribute	Description
IsSystemArea	The owner of the storage area.
ShortDescription	A caption of the database.
TokenId	A unique identifier populated by BMC Discovery products and used by the Reconciliation Engine to identify instances

# Storage entity modeling

This section details how to model storage entities and their relationship to the computer systems that will utilize the services provided.

The following topics are provided:

- Characteristics of storage entities and devices (page 60)
- Modeling a tape drive (page 60)
- Modeling a DASD (page 61)
- Modeling a Virtual disk (page 62)
- Modeling a NAS device (page 65)
- Modeling raw storage (page 67)

# Characteristics of storage entities and devices

Storage entities and devices that you want to model in your environment might include tape drives, disk drives, virtual disks, network-attached storage (NAS), and pool of storage subsystems.

## Modeling a tape drive

A tape drive is modeled as an instance of `BMC_TapeDrive` (derived from `BMC_Media`).

### Logical identity of `BMC_TapeDrive`

Table 5-1 describes key attributes of a tape drive.

**Table 4-1: Key attributes of a tape drive**

Attribute	Usage
Name	Identifies the instance. The unique name is not necessarily human-readable.
NameFormat	Specifies the heuristic used to generate the Name value.
SystemName	Specifies the name of the system in which the component resides. This attribute is automatically populated from the related CI when a weak relationship is created between the computer system and the tape drive.

### Additional attributes for `BMC_TapeDrive`

Table 5-2 describes additional attributes of a tape drive.

**Table 4-2: Additional attributes of a tape drive**

Attribute	Description
Description	The description of the instance.
ManufacturerName	The name of the vendor.
MediaType (not inherited)	The type of media. Its value is always Removable Media.
Model	The tape drive model.
ShortDescription	A caption of the instance.

## Tape drive instance

Table 5-3 illustrates an example instance.

**Table 4-3: Example of a tape drive instance**

Attribute	Value
Description	003590.B1A.IBM.13.000000044832.0080
ManufacturerName	IBM
MediaType	Removable Media
Model	3590-1
Name	003590.B1A.IBM.13.000000044832.0080
NameFormat	Mainframe
ShortDescription	003590.B1A.IBM.13.000000044832.0080
SystemName	003590.B1A.IBM.13.000000044832

## Modeling a DASD

A direct access storage device (DASD) is modeled as an instance of BMC\_DiskDrive (derived from BMC\_Media).

### Logical identity of BMC\_DiskDrive

Table 5-4 describes key attributes of a DASD.

**Table 4-4: Key attributes of DASD**

Attribute	Usage
Name	Identifies the instance of the disk drive. Use this attribute to specify the unique name of the instance; not necessarily human-readable.
NameFormat	Specifies the heuristic used to generate the Name value.
SystemName	Specifies the name of the system in which the component resides. This attribute is automatically populated from the related CI when a weak relationship is created between the computer system and the tape drive.

### Additional attributes for BMC\_DiskDrive

Table 5-5 describes additional attributes of a DASD.

**Table 4-5: Additional attributes of DASD**

Attribute	Description
Description	The description of the instance.
ManufacturerName	The name of the mainframe vendor.
MediaType (inherited from BMC_Media)	The type of media. Its value is always Fixed Hard Disk.

**Table 4-5: Additional attributes of DASD (Continued)**

Attribute	Description
Model	The DASD model.
SerialNumber	The manufacturer-allocated number used to identify the instance.
ShortDescription	A caption of the instance.

## DASD instance

Table 5-6 illustrates an example of an DASD instance.

**Table 4-6: Attributes of a DASD instance**

Attribute	Value
Name	002105.000.IBM.13.000000025559.0B46
NameFormat	Mainframe
SystemName	002105.000.IBM.13.000000025559
Description	002105.000.IBM.13.000000025559.0B46
ManufacturerName	IBM
MediaType	Fixed Hard Disk
Model	3390
SerialNumber	ADR071
ShortDescription	ADR071

## Modeling a Virtual disk

A virtual disk refers to storage allocated to a virtual machine for use by the operating system. The file system is laid on the provided virtual disk. Virtual disks are created from a physical hard drive or allocated from NAS/SAN infrastructure. A virtual disk is modeled as an instance of `BMC_LogicalDisk`.

## Logical identity of BMC\_LogicalDisk (virtual disk)

Table 4-7 describes key attributes of a virtual disk.

**Table 4-7: Key attributes of a virtual disk**

Attribute	Usage
Name	Identifies the logical disk with respect to the virtual machine to which the disk is allocated. The following list provides examples of the values that the Name attribute might contain, depending on the operating system: <ul style="list-style-type: none"> <li>■ Windows—the name of the drive, for example, E:\</li> <li>■ UNIX—the access path, for example, '/dev/...'</li> </ul>
NameFormat	Specifies the heuristic used to generate the Name value. When this attribute is set to 'OS Device Name', the Name attribute is populated with a uniquely identifiable device name.
SystemName	Name of the computer system to which the logical device belongs.

## Additional attributes of BMC\_LogicalDisk

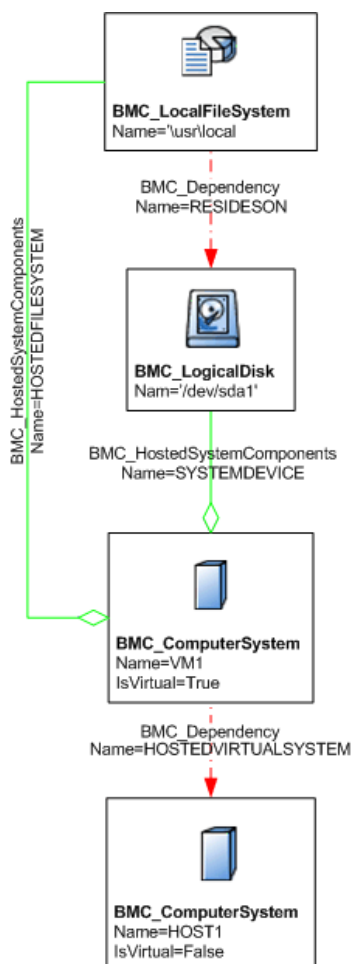

Table 4-8 describes additional attributes of a virtual disk.

**Table 4-8: Additional attributes of a virtual disk**

Attribute	Description
BlockSize	Size of the blocks (in bytes) that form the given storage extent. If the block size is variable, make sure that you specify the maximum block size in bytes. If the block size is unknown, specify a value of 1.
NumberOfBlocks	Total number of logical contiguous blocks that form the given storage extent. You can calculate the total size of the storage extent by multiplying the BlockSize by the value of the NumberOfBlocks attribute. If the BlockSize is 1, this property is the total size of the Extent.
AvailableCapacity	Indicates the total amount of free space (in bytes) that is available on the given storage extent. If the free space is unknown, specify a value of 0.
ConnectionType	The storage protocol used to communicate with the storage controller, for example, SCSI, iSCSI, FCoE, and Infiniband.

## Modeling virtual disk allocated to a virtual machine

Model the virtual disk allocated to a virtual machine (VM) using the BMC\_LogicalDisk class and create an association to the virtual machine using the SYSTEMDEVICE relationship. Figure 4-1 on page 64 illustrates a simple scenario where a virtual disk is allocated to a VM and a file system is installed on it.

**Figure 4-1: Modeling virtual disk allocated to virtual machine**

## Modeling logical disk allocated to a virtual machine from a resource pool

You can model storage resources that are allocated from the storage resource pool using the **BMC\_ResourcePool** class. This class has attributes to store the capacity and utilization properties of the storage resources. The resource pool should be related to the storage system that hosts it using **HOSTEDRESOURCEPOOL** relationship.

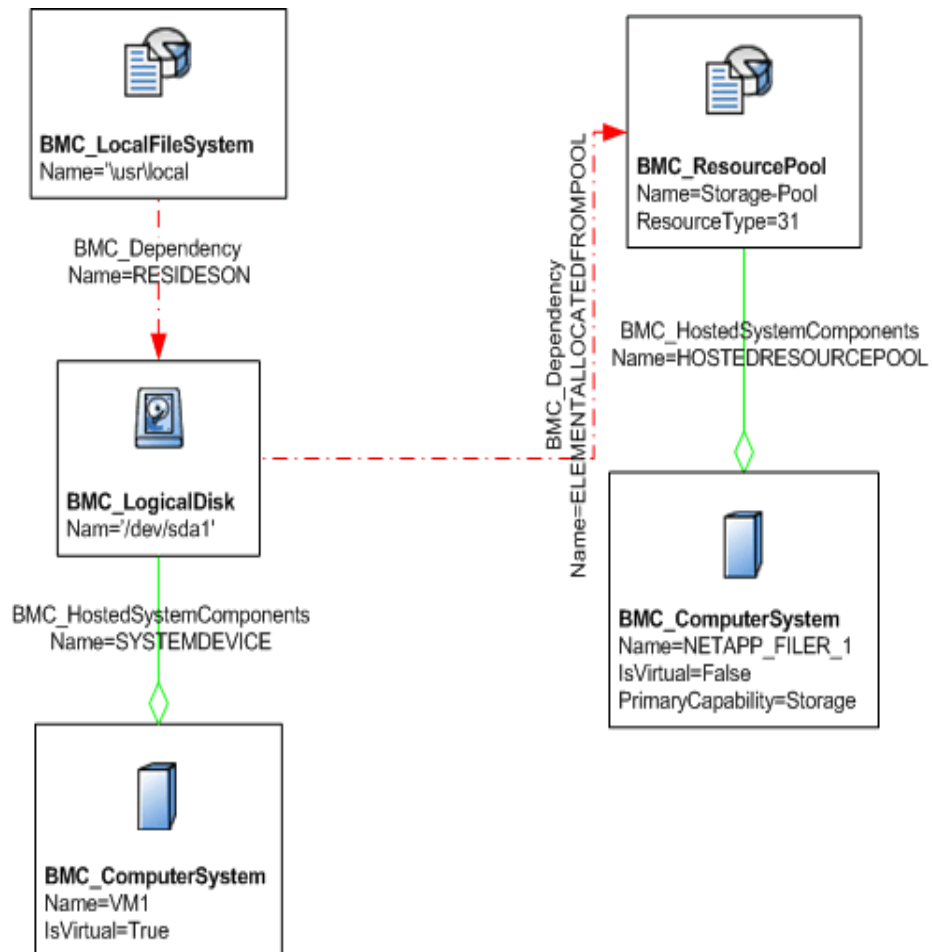

You might have one or more virtual disks in your environment that are created from a storage system and are allocated to virtual machines. You model such virtual disks by using the **BMC\_LogicalDisk** class. You can associate this class to the hosted virtual machine by using the **SYSTEMDEVICE** relationship. You will also need to associate the logical disk to the resource pool where it comes from by using the **ELEMENTALLOCATEDFROMPOOL** relationship.

You should model the file system laid by the virtual computer system on the logical disk by using the **BMC\_LocalFileSystem** class. You associate this class to the logical disk by using the **RESIDESON** relationship. Associate the **BMC\_ComputerSystem** class by using the **HOSTEDFILESYSTEM** relationship.

Figure 4-2 illustrates an example of a logical disk that is allocated from a resource pool and is hosted on a storage system.

**Figure 4-2: Modeling a logical disk**

## Modeling a NAS device

This section describes how to model simple and complex NAS devices.

### Modeling a simple NAS device

To model a NAS device in a simple scenario, represent the NAS device using the `BMC_ComputerSystem` class. Set the `PrimaryCapability` attribute of the class to `Storage`. Figure 4-3 on page 66 illustrates how to model a simple NAS device.

Figure 4-3: Modeling NAS device—simple

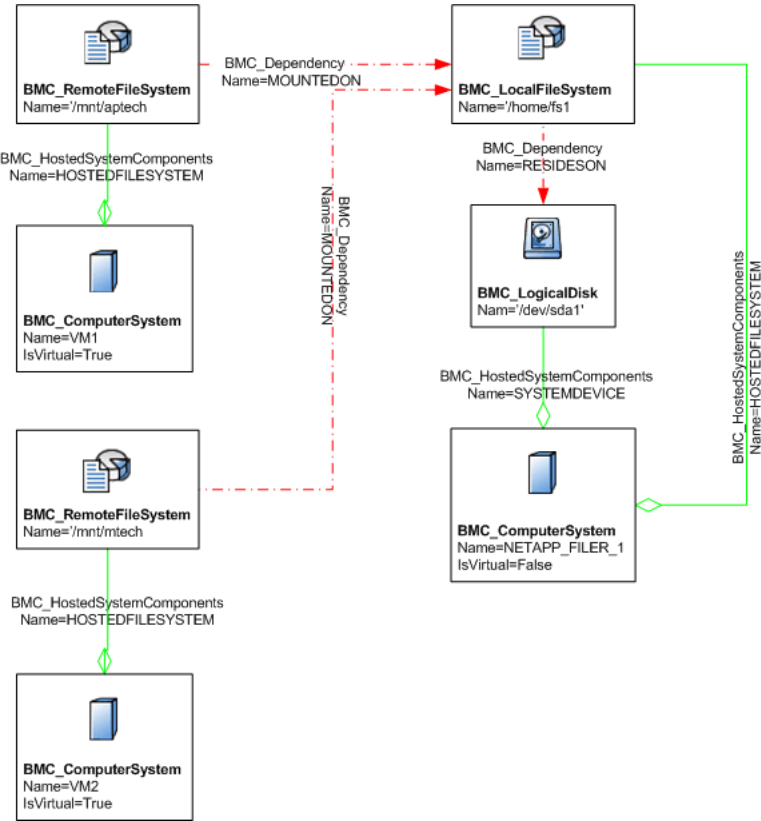

## Modeling a remote mounted file system

When a virtual machine mounts a file system from a network-attached storage (NAS) device, model the file system by using the BMC\_RemoteFileSystem class. You model the file system on the NAS device by using the BMC\_LocalFileSystem class. You relate the remote file system to the local file system by using the MOUNTEDON relationship. Associate the remote file system with the computer system by using the HOSTEDFILESYSTEM relationship.

You can model various logical storage components in the NAS device by using the BMC\_LogicalDisk class and the BMC\_ResourcePool class. Figure 4-4 on page 66 illustrates an example where a virtual machine accesses a NAS device and uses the NAS to mount a file system from it.

Figure 4-4: Modeling a remote mounted file system

# Modeling raw storage

A raw storage volume might be directly mapped to a physical or virtual machine, provided a storage volume manager is present, from the host computer over the network, from SAN infrastructure, or a physical machine.

The virtualization platform, in order to access such volumes over the network, uses protocols such as iSCSI or Fiber Channel. Raw storage volume is modeled as an instance of `BMC_storageVolume`.

## Logical identity of `BMC_storageVolume` (raw storage volume)

Table 4-9 describes key attributes of a raw storage volume.

**Table 4-9: Key attributes of a raw storage volume**

Attribute	Usage
Name	Identifies the storage volume allocated to a virtual machine. A unique device identifier that is returned from the storage system is populated in this attribute.
NameFormat	Specifies the heuristic used to generate the Name value.
SystemName	Name of the computer system on which the storage volume is hosted.

## Additional attributes of `BMC_storageVolume`

Table 4-10 describes additional attributes of a raw storage volume.

**Table 4-10: Additional attributes of a virtual disk**

Attribute	Description
LUNID	A logical unit number (LUN) is the identifier of a device, which is being addressed by the SCSI protocol or similar protocols, such as Fiber Channel and iSCSI.
BlockSize	Size of the blocks (in bytes) that form the given storage extent. If the block size is variable, make sure that you specify the maximum block size in bytes. If the block size is unknown, specify a value of 1.
NumberOfBlocks	Total number of logical contiguous blocks that form the given storage extent. You can calculate the total size of the storage extent by multiplying BlockSize by the value of the NumberOfBlocks attribute. If the BlockSize is 1, this property is the total size of the Extent.
AvailableCapacity	Indicates the total amount of free space (in bytes) that is available on the given storage extent. If the free space is unknown, specify a value of 0.
ConnectionType	The storage protocol used to communicate with the storage controller, for example, SCSI, iSCSI, FCoE, and Infiniband.

## Modeling storage volume allocated to a virtual machine

You can model storage volume allocations to virtual machines using the BMC\_StorageVolume class and associate it to the containing computer using the SYSTEMDEVICE relationship. Figure 4-5 on page 68 illustrates a simple scenario where a storage volume is used in a virtual machine.

**Figure 4-5: Modeling storage volume allocated to virtual machine**

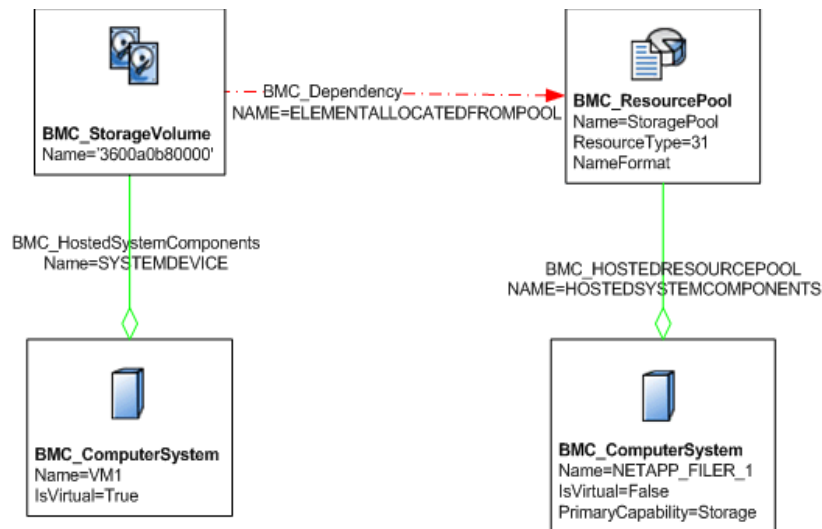

## Modeling storage volume allocated to a virtual machine from a resource pool

Model virtual machine, storage resource pool, and the storage system, as described in Modeling logical disk allocated to a virtual machine from a resource pool (page 64).

You should model the raw device that is mapped directly to a virtual machine by using the BMC\_StorageVolume class. You associate this class to the resource pool by using the ELEMENTALLOCATEDFROM relationship and the BMC\_ComputerSystem class that represents the virtual system by using the SYSTEMDEVICE relationship.

Figure 4-6 on page 69 illustrates an example of allocating a storage volume to a virtual machine from a storage system.

Figure 4-6: Modeling a raw storage volume

## Relationships for storage systems

Table 4-11 describes the relationships used for storage systems. Use the value listed in the table to specify the name for a relationship between any two storage classes.

Table 4-11: Relationships for storage systems

Relationship	Relationship class	Value of Name attribute
Storage subsystem and an operating system	BMC_Dependency	STORAGESUBSYSTEMOS
Storage subsystem and a DASD	BMC_HostedSystemComponents	STORAGESUBSYSTEMDASD
Storage subsystem and a tape drive	BMC_HostedSystemComponents	STORAGESUBSYSTEMTAPE
File system hosted on a physical or virtual machine	BMC_HostedSystemComponents	HOSTEDFILESYSTEM
A logical disk allocated to a virtual machine	BMC_HostedSystemComponents	SYSTEMDEVICE
A file system residing on a logical disk	BMC_Dependency	RESIDESON
A storage volume allocated to a virtual machine	BMC_HostedSystemComponents	SYSTEMDEVICE
Relationship between a remote mounted file system such as NFS and the file system where it actually resides.	BMC_Dependency	MOUNTEDON

# Network topology modeling

This section details how to model network topology, including components on a subnet, network interfaces, and LAN and WAN networks.

The following topics are provided:

- Network topology characteristics (page 72)
- L3 topology and IP connectivity modeling (page 72)
- L2 topology and physical connectivity modeling (page 73)
- Network topology and LAN and WAN network modeling (page 75)

# Network topology characteristics

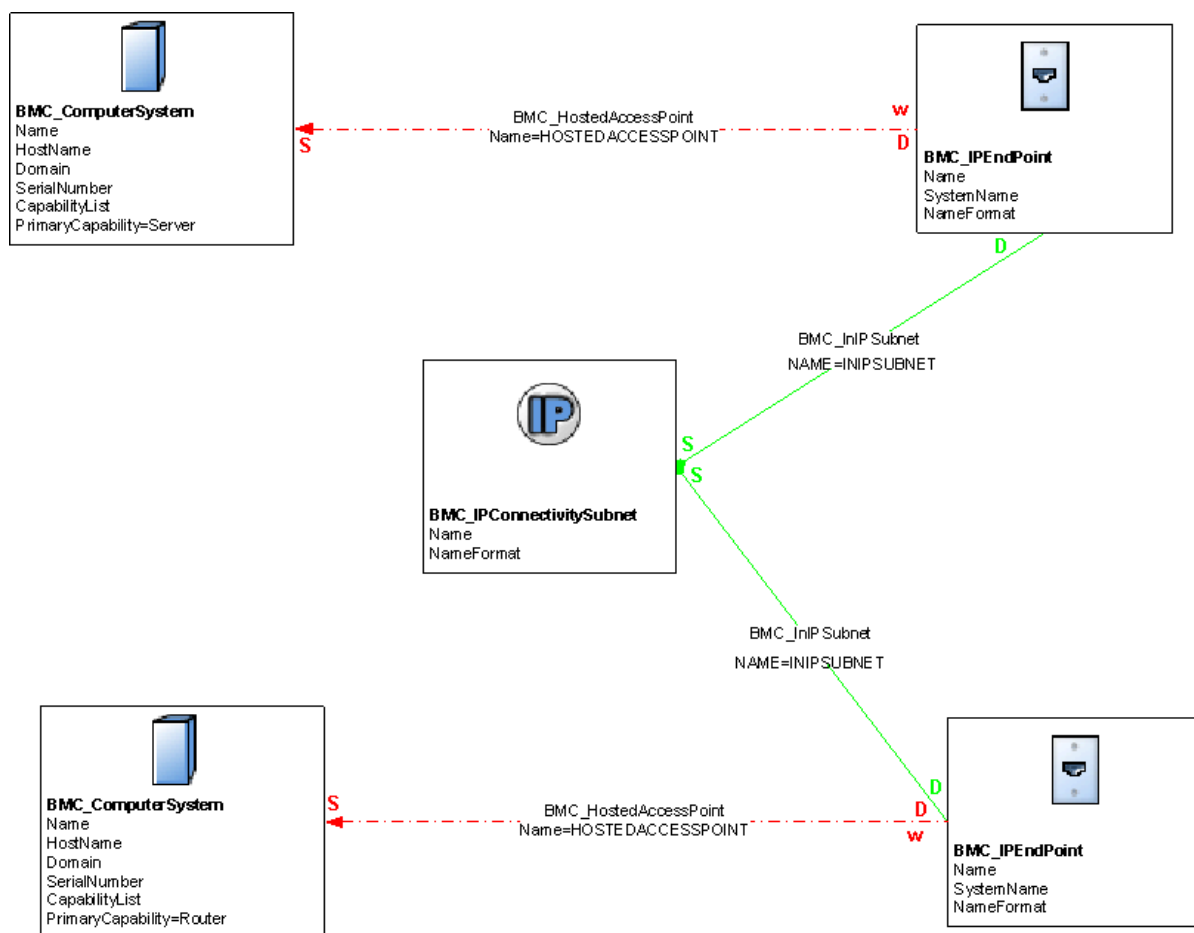

Topologies are based on the `BMC_ConnectivityCollection` class, which are collections of `BMC_ProtocolEndpoint` (communication points from which data may be sent or received) of the same type and which can communicate with each other. Logical groupings of these connectivity collections enable users to define the scope of LAN and WAN networks.

## L3 topology and IP connectivity modeling

A `BMC_IPConnectivitySubnet` instance represents a group of related `BMC_IPEndpoint` instances that can communicate with each other as members of a subnet and describes the characteristics of the subnet.

Figure 6-1 illustrates a server and a router that belong to the same subnet.

**Figure 5-1: Illustrative model of components on a subnet**

## Logical identity of BMC\_IPConnectivitySubnet

Table 6-1 describes key attributes of BMC\_IPConnectivitySubnet.

**Table 5-1: Key attributes for BMC\_IPConnectivitySubnet**

Attribute	Usage
Name	Identifies the IP address of the entire subnet, formatted according to the appropriate convention as defined in the AddressType attribute. When AddressType is 1 (IPv4), the Name must be built by concatenating the SubnetNumber and SubnetMask separated by a /.
NameFormat	Specify the heuristic used to generate the Name value, which must be set to IP.

## Additional attributes for BMC\_IPConnectivitySubnet

Table 6-2 describes attributes that provide additional information about BMC\_IPConnectivitySubnet.

**Table 5-2: Additional attributes for BMC\_IPConnectivitySubnet**

Attribute	Description
AddressType	An enumeration that describes the format of the Name and SubnetNumber properties in IPConnectivitySubnet: <ul style="list-style-type: none"> <li>■ 0—Unknown</li> <li>■ 1—IPv4</li> <li>■ 2—IPv6</li> </ul>
PrefixLength	A prefix length for IPv6 addresses in the IP subnet (AddressType property is 2).
SubnetMask	The mask for the starting address of the IPv6 IP subnet (AddressType is 1).
SubnetNumber	The IP address of the entire subnet; must be equal to the Name attribute.

## Relationships for components on a subnet

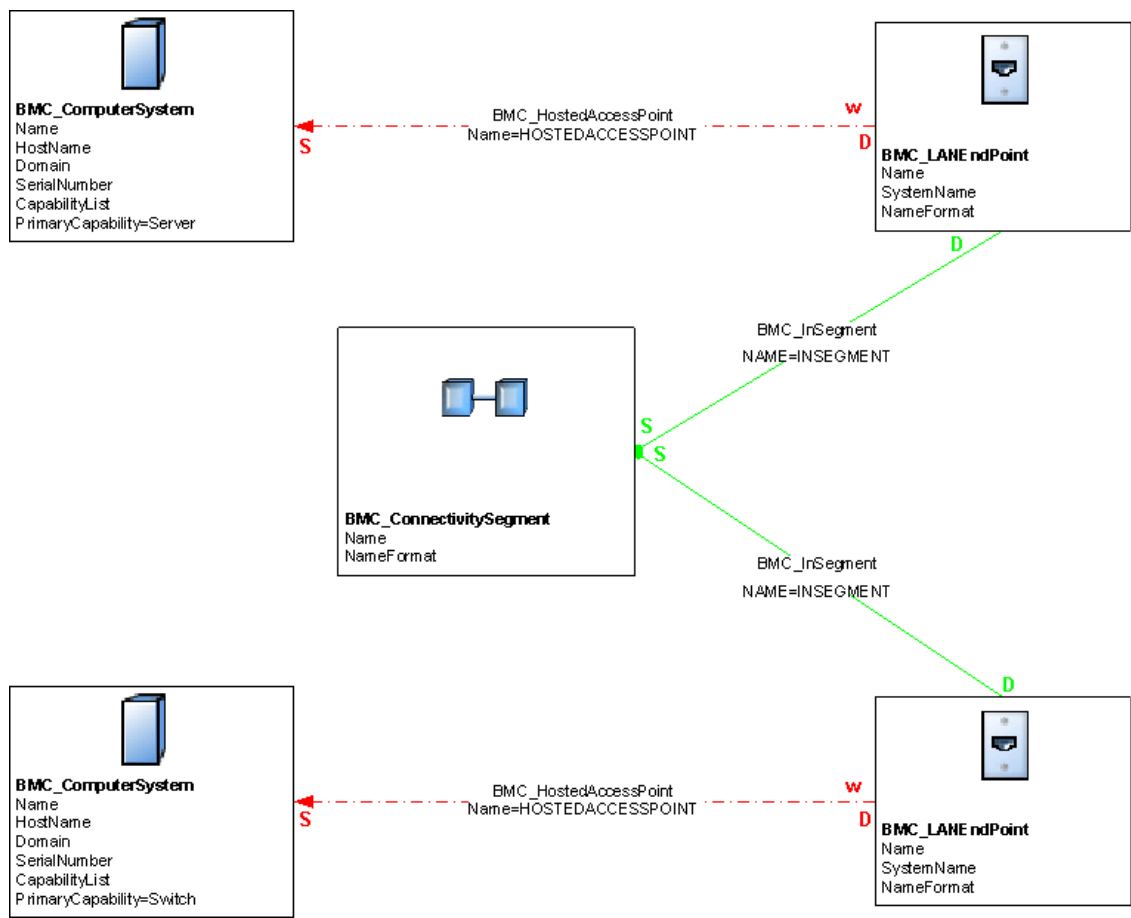

BMC\_IPEndpoint instances are associated to the BMC\_IPConnectivitySubnet to which they belong through the BMC\_InIPSubnet relationship.

# L2 topology and physical connectivity modeling

A BMC\_ConnectivitySegment instance represents a group of related instances of BMC\_LANEndpoint of a particular type (such as Ethernet, token ring, or fiber channel) that can intercommunicate without the assistance of bridging or routing services. They are sometimes referred to as members of the same collision domain. The class describes the characteristics of the group, or segment.

Figure 6-2 illustrates a server and a switch, with the server having one NIC directly connected to a network interface of the switch.

Figure 5-2: Illustrative model of a network interface

Logical identity of BMC\_ConnectivitySegment

Table 6-3 describes key attributes of BMC\_ConnectivitySegment.

Table 5-3: Key attributes of BMC\_ConnectivitySegment

Attribute	Usage
Name	Identifies the connectivity segment, which uses the following information and generates a hash code as resulting value: <ul style="list-style-type: none"><li>■ The list of physical addresses that belong to the segment.</li><li>■ The name of the LAN instance to which the segment belongs.</li></ul>
NameFormat	Specifies the heuristic used to generate the Name value, which must be set to OID.

## Additional attributes for BMC\_ConnectivitySegment

Table 6-4 describes attributes that provide additional information about BMC\_ConnectivitySegment.

**Table 5-4: Additional attributes for BMC\_ConnectivitySegment**

Attribute	Description
ConnectivityType	An enumeration that describes the type of technology used: <ul style="list-style-type: none"> <li>■ 0—Unknown</li> <li>■ 1—Other</li> <li>■ 2—Ethernet</li> <li>■ 3—Token Ring</li> <li>■ 4—FDDI</li> <li>■ 5—Fiber Channel</li> </ul>
Count	The current number of endpoints connected to this segment. When this value equals 2 it indicates a direct connection between the two network ports interconnected by means of the segment.

## Relationships for network interfaces

Instances of BMC\_LANEndpoint are associated to the BMC\_ConnectivitySegment to which they belong through the BMC\_InSegment relationship.

# Network topology and LAN and WAN network modeling

LAN and WAN networks do not have a well-known identifier, such as an IP address or mask for an IP subnet. These networks are characterized by the list of machines that can intercommunicate at the physical level without crossing the boundaries of gateways. This description includes the infrastructure network devices (switches, hubs) that enable these machines to communicate. In the CDM, LANs and WANs are captured by entities that aggregate that list of IP subnets.

Figure 6-3 illustrates a LAN that aggregates IP subnets.

Figure 5-3: Illustrative model of a LAN

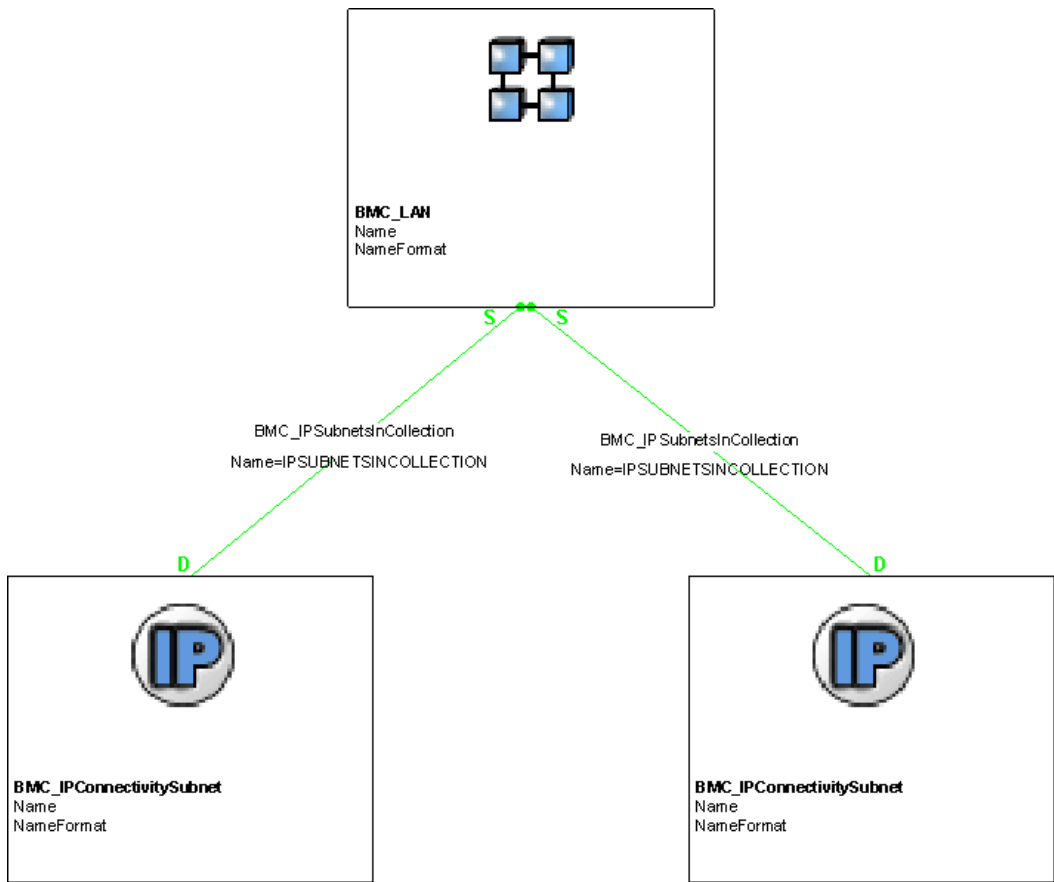

Figure 6-4 illustrates an example of a WAN that aggregates IP subnets.

Figure 5-4: Illustrative model of a WAN

## Logical identity of BMC\_LAN

You can model a virtual LAN by using the BMC\_LAN class and setting its IsVirtual attribute to True. Table 6-5 describes key attributes of BMC\_LAN.

**Table 5-5: Key attributes of BMC\_LAN**

Attribute	Usage
Name	Identifies the LAN, computed from the list of IP subnets that make up the LAN. The name for the LAN is the lexicographically lower value of the names of IP subnets.
NameFormat	Specifies the heuristic used to generate the Name value, which must be set to OID.

## Logical identity of BMC\_WAN

Table 6-6 describes key attributes of a BMC\_WAN.

**Table 5-6: Key attributes of BMC\_WAN**

Attribute	Usage
Name	Identifies the WAN, computed from the list of IP subnets that make up the WAN. The name for the WAN is the lexicographically lower value of the names of IP subnets.
NameFormat	Specifies the heuristic used to generate the Name value, which must be set to OID.
WANType	Specifies the enumeration that describes the type of technology used: <ul style="list-style-type: none"><li>■ 0—Unknown</li><li>■ 1—Other</li><li>■ 2—ATM</li><li>■ 3—Frame relay</li></ul>

## Appendix

# A Summary of changes to the Common Data Model

This section lists all the change to the Common Data Model in the 7.6.00 release. The following topics are provided:

- Changes to the BMC Atrium CMDB 7.5.00 Common Data Model (page 80)
- Changes to the BMC Atrium CMDB 7.6.00 Common Data Model (page 81)
- Changes to the BMC Atrium CMDB 7.6.03 Common Data Model (page 82)
- Changes to the BMC Atrium CMDB 7.6.04 Common Data Model (page 83)

# Changes to the BMC Atrium CMDB 7.5.00 Common Data Model

The following CI classes were added to the CDM in BMC Atrium CMDB 7.5.00:

**Table A-1: New CI classes in BMC Atrium CMDB 7.5.00**

CI class	Description
BMC_Offering	stores information about service offerings that are part of a high-level service
BMC_ServiceLevelTarget	stores information about Service Level Targets (SLTs)
BMC_Contract	acts as a container object made up of line items that establish a specific agreement between a provider and a customer
BMC_ContractLine	stores contract line items that establish specific agreements between the provider and the customer
BMC_Transaction	specifies a single transaction initiated by an end user or system
BMC_ResourcePool	serves as a logical entity (with associated controls) provided by the host system to allocate and assign resources
BMC_ResourceAllocationSettingData	represents settings that specifically relate to an allocated resource that is outside the scope of the CIM class (which is typically used to represent the resource itself)
BMC_VirtualSystemSettingData	defines the virtual aspects of a virtual system through a set of virtualization-specific properties
BMC_Settings	represents additional attributes of a given CI that are not part of the CI type definition

The following relationship classes were added to the CDM in BMC Atrium CMDB 7.5.00:

**Table A-2: New relationship classes in BMC Atrium CMDB 7.5.00**

Relationship class	Description
BMC_Impact	represents a generic association used to establish impact relationships between objects
BMC_SettingsOf	represents the association between ManagedElements and applicable setting data
BMC_ServiceRealizedByOffering	defines the relationship between the business service and the offering
BMC_OfferingMeasuredBy	defines the relationship between the offering and the Service Level Target
BMC_ContractComponent	defines the relationship between the contract and the contract line item

The `BMC_VirtualSystem` class was removed. The `VirtualSystemType` attribute from the removed class was added to `BMC_ComputerSystem`. The `TotalMemory` attribute was deleted. Your virtual system information should be stored in `BMC_ComputerSystem`.

## Changes to the BMC Atrium CMDB 7.6.00 Common Data Model

The following classes and attributes have been added in BMC Atrium CMDB 7.6.00.

**Table A-3: New classes and attributes in BMC Atrium CMDB 7.6.00**

New Class	Existing class	New attributes
BMC_Geneology	Not applicable	No attributes
Not applicable	BMC_VirtualSystemSettingData	ActualDecommissionDate, ActualProvisionDate, ProposedDecommissionDate

### Attributes that have been moved

In BMC Atrium CMDB 7.6.00, the `isVirtual` attribute was moved from the `BMC_ComputerSystem` class to the `BMC_System` and `BMC_SystemComponent` classes. This move expands the virtualization scope beyond computer systems, enabling you to model potential future virtualizable entities, such as applications. Because `BMC_ComputerSystem` is a subclass of the `BMC_System` class, the `isVirtual` attribute is still available in the `BMC_ComputerSystem` class.

### Attributes that have been hidden

The `Dimensions` attribute in the `BMC_ComputerSystem` class is hidden in the Console view but can be seen in the Class Manager.

# Changes to the BMC Atrium CMDB 7.6.03 Common Data Model

The following classes and attributes have been added in BMC Atrium CMDB 7.6.03.

**Table A-4: New classes and attributes in BMC Atrium CMDB 7.6.03**

New class	Existing class	New attributes
BMC_MFCouplingFacility	Not applicable	CFRMName, CFRMSiteName, NodeDescriptor, Storage
BMC_StorageSubsystem	Not applicable	No attributes added
Not applicable	BMC_BaseElement	ADDMIntegrationId, MarketVersion, NormalizationStatus, ReconciliationMergeStatus
Not applicable	BMC_ComputerSystem	IsUnqualified
Not applicable	BMC_IPEndpoint	IsUnqualified
Not applicable	BMC_ApplicationSystem	MFJobName, MFServerId
Not applicable	BMC_BaseRelationship	ImpactSourceId, ImpactDestinationId, NormalizationStatus, ReconciliationMergeStatus
Not applicable	BMC_HostesAccessPoint	IsUnqualified
BMC_MFCouplingFacility	Not applicable	CFRMName, CFRMSiteName, NodeDescriptor, Storage

## Classes that have been deprecated

The BMC\_Impact relationship class is deprecated and is mapped to the BMC\_BaseRelationship class. The HasImpact attribute of the BMC\_BaseRelationship class is set to “Yes” and the Name attribute is set to “ImpactOnly”.

# Changes to the BMC Atrium CMDB 7.6.04 Common Data Model

The following classes and attributes are added in BMC Atrium CMDB 7.6.04.

**Table A-5: New classes and attributes in BMC Atrium CMDB 7.6.04(Sheet 1 of 2)**

New class	Existing class	New attributes
Not applicable	BMC_BaseElement	ReconciliationIdType, LastUpdatedDatasetId
Not applicable	BMC_BaseRelationship	ReconciliationIdType, LastUpdatedDatasetId
Not applicable	BMC_Offering	IsLocked, WarrantyLevel
Not applicable	BMC_ServiceLevelTarget	SLTClassification
Not applicable	BMC_Document	DocumentPurpose, ExecutionDate, TerminationDate
Not applicable	BMC_BusinessService	ServiceLifeCycle
Not applicable	BMC_ContractLine	Quantity, PerPricePeriod, PriceAmount, PriceUOM, ServiceRequestId
Not applicable	BMC_FileSystem	FileSystemSize, AvailableSpace, FileSystemType, BlockSize
Not applicable	BMC_Collection	IsVirtual
Not applicable	BMC_ResourcePool	HighWaterMark, LowWaterMark, MaxConsumableResource, MinConsumableResource
BMC_ServiceOffering	Not applicable	IsDefault
BMC_RequestableOffering	Not applicable	IsAddOn, DeliveryRO
BMC_ServiceOfferingInstance		ActualDecommissionDate, ProposedDecommissionDate, ProvisionDate
BMC_Option		ChoiceSelectionMode, FulfillmentDetails, OptionType
BMC_OptionChoice		Sequence, IsDefault
BMC_FinancialElement		PerTimePeriod, UOM
BMC_Cost		CostAmount, CostDeliveredFlag

**Table A-5: New classes and attributes in BMC Atrium CMDB 7.6.04(Sheet 2 of 2)**

New class	Existing class	New attributes
BMC_Price		IsLocked, MaximumQuantity, MinimumQuantity, PriceAmount, PriceLifeCycle, PriceQuantity
BMC_StorageExtent	Not applicable	BlockSize, NumberOfBlocks, AvailableCapacity, ConnectionType
BMC_LogicalDisk	Not applicable	No attributes added
BMC_StorageVolume	Not applicable	LUNID
BMC_Tag	Not applicable	IsCategory, CategoryName
Not applicable	BMC_Offering	IsLocked, WarrantyLevel

## Classes and attributes that are deprecated

The `OfferingType` attribute of the `BMC_Offering` class is deprecated. Use the `BMC_ServiceOffering` or the `BMC_RequestableOffering` derived classes instead of the `BMC_Offering` class to store `OfferingType` information for a service.
